Method of silver impregnation for nervous tissue embedded in paraffin

SERGE DUCKETT From Maida Vale Hospital for Nervous Diseases, London

The aim of the silver impregnation methods for paraffin-embedded sections of nervous tissue is to combine fineness of histological detail with an easy method of processing.

The following method is presented here because of its rapidity, reliability, staining quality, and utility as a general purpose stain. The basic technique, without the variations, was devised by Fincher (1932) on the basis of Hortega's silver carbonate impregnation method for astrocytes and its purpose was to stain cerebral tumours.

METHOD

1. Paraffin sections, of 5 to 8 µ for pathological studies and of 10 to 20 µ for anatomical studies, are mounted on albuminized slides a few hours before use. The sections are then slowly brought through xylo (5 minutes), absolute alcohol (5 minutes), and alcohol 95° (5 minutes), and washed in distilled water.

2. Mordant in the following solution at 60°C. until yellow.
   - Silver nitrate 2% .......................... 30 ml.
   - Pyridine ................................. 10 drops
   - Absolute alcohol ........................ 15 drops

This usually takes 30 minutes. I prefer not to pre-warm my solution. Prolonged mordanting gives too dark a picture.

3. Wash quickly in 95° alcohol.

Received for publication 31 March 1964.

*Presently clinical fellow with the Medical Research Council.

A simple constant-infusion apparatus—continued.

At present two of these models are being used for the injection of tritiated thymidine into rats at a rate of 0.5 ml. per 25 hours (Foot, 1963).

The advantages of the present device are its simplicity, cheapness, accuracy, 'foilproofness', and the minute amounts that can be injected. Its working can also be checked easily by observing the rotation of the micrometer head. Its disadvantage is that a separate motor is required for each different speed but these are cheap and can be changed in a few moments.

The author is in receipt of a grant from the British Empire Cancer Campaign.

REFERENCES

4. Impregnate in the following solution at 60°C. until a dark amber colour. If the solution has been pre-warmed this takes from 15 to 30 minutes; if not it may take up to an hour, at which time the section should be taken out no matter what colour it is.

   - Hortega's strong silver carbonate (lithium or sodium)* .......................... 30 ml.
   - Pyridine ................................. 10 drops
   - Absolute alcohol ........................ 15 drops

5. Wash rapidly in 95° alcohol.

6. Reduce in 10% formol for one to two minutes.

7. Wash in distilled water.

8. If desired tone in a 0.2% gold chloride solution.

9. Wash in distilled water.

10. Leave in a 2% oxalic acid solution for a few minutes until the sections become reddish. This step accentuates the staining of axones.

11. Fix, if desired, in a 5% solution of sodium thiosulphate.

12. Wash in distilled water, dehydrate, clear, and mount in balsam.

---

*a Lithium carbonate solution: To 5 ml 10% silver nitrate add 20 ml of a saturated solution of lithium carbonate and then drop by drop add 28% ammonia water barely to dissolve the precipitate. Bring volume to 75 ml with distilled water and filter. Keep in brown bottle.
b Sodium carbonate solution: To 5 ml 10% silver nitrate add 20 ml 3% sodium carbonate solution and then drop by drop add 28% ammonia water barely to dissolve the precipitate. Add about 20 ml distilled water and filter, bringing volume to 45 ml. Keep in brown bottle.

Hypertrophied oligodendrocytes in cerebral white matter. Variant 2 × 400 (mordanting 45 minutes; impregnation 45 minutes).

**FIG. 3**

Climbing fibres ascending through the granular layer and surrounding the base of the Purkinje cells. Above are seen the horizontal fibres of the basket cells. Variant 2 × 400 (mordanting half an hour; impregnation half an hour).

**VARIANTS ON THE METHOD**

There are a number of variants to this technique which when employed bring out different morphological features of the section (Table I). These are divided into two groups, the first one uses Hortega's strong lithium silver carbonate solution, the second Hortega's strong sodium silver carbonate solution. Thus six sections can be placed in a Coplin jar and then carried on through the various steps until the sections have been mordanted (step 2). Then three sections are impregnated with the lithium silver carbonate solution (variants 1, 2, 3) and the others through the sodium silver carbonate solution (variants 4, 5, 6). Variants 1 and 4 are reduced in 10% formol and mounted in balsam. Variants 2 and 5 are
Technical methods

Variant 3 and 6 are reduced in formol, toned in gold chloride, washed in 2% oxalic acid, dehydrated and mounted in balsam.

Variants 1 and 4, the untoned sections, show well the axons and glial fibres (Fig. 1). Variant 2 shows the glia (Fig. 2), the more delicate fibrillary systems (Fig. 3), and neurons. Variant 3 shows the axons well, and has been useful in showing the nerve fibres coursing through muscle (Fig. 4). Variant 5 is a reticulin stain (Fig. 5). Variant 6 also shows the reticulin, as reddish fibres against a grey background, and gliosis (Fig. 6). With all these variants the staining may benefit from varying the times for mordanting and impregnating, and the reducing formol solution can be diluted to 1%, 5%, or 20%.

I would like to thank Drs. W. McMenemey, A. G. E. Pearse, C. Margolis, and John Prineas for their help.
