Efficacy of different selective media for the isolation of salmonellae from faeces

J. ZAJC-SATLER AND S. BANIĆ
From the Institute of Microbiology, Medical Faculty, Ljubljana, Yugoslavia

SYNOPSIS Comparative results obtained in isolating salmonellae from faeces by the use of tetra-thionate broth, MS, and MM enrichment medium are given. The best results were obtained by tetra-thionate broth prepared from infusion broth. The MS as well as the MM medium increased the total number of positive results.

There are many efficient selective media for the isolation of salmonellae, but none of them is as efficient as desired. To obtain the best results many authors recommend the use of two or three different enrichment media in addition to the direct plates (Sen, 1964; Guinée and Kampelmacher, 1962; Taylor, Buttiaux, and Catsaras, 1963). The purpose of this study was to compare the efficacy of the MM (Rappaport, Konforti, and Navon, 1956) and MS (Banić, 1963) media with that of the Müller-Kauffmann enrichment medium and of direct plating for the isolation of salmonellae from faeces.

MATERIALS AND METHODS

MEDIA The Wilson-Blair agar and SS agar were prepared according to Priručnik mikrobioloških metoda (Manual of Microbiological Methods, 1953), tetra-thionate broth according to the formula given by Kauffmann (1941), and the MM medium according to the formula given by Rappaport et al. (1956).

The MS medium, which is composed of nutrient broth Difco + 0.2% yeast extract Difco + 0.05% sodium hydrogen selenite (NaHSeO₃) (Merck) + 3.4% MgCl₂, was prepared as described in a previous paper (Banić, 1963). It should be mentioned that the stock solution of 40% MgCl₂ used in the preparation of the MM medium was made up according to the method of Rappaport et al. (1956) so that 100 g. of MgCl₂ (the whole content of a newly-opened bottle) was dissolved in 250 ml. of distilled water, whereas the stock solution of 40% MgCl₂ for the MS medium was prepared by placing 100 g. of MgCl₂ (the whole content of a newly-opened bottle) in a sterile measured cylinder and then distilled water was added to make the solution up to 250 ml.

Altogether, 1,090 specimens of faeces were examined. Each specimen was first seeded on a direct Wilson-Blair and SS agar plate. Then about 1 g. of the faeces was emulsified in 10 ml. of distilled water, and four drops of this suspension were dropped into a tube of each of the enrichment media. After incubation for 18 hours a loopful of each of the enrichment media was plated on to Wilson-Blair and SS agar. The plates were incubated overnight and then examined for salmonellae together with the direct plates according to the standard methods.

RESULTS

Two hundred Salmonella strains were isolated. Among them the following Salmonella species were identified: 65 strains of S. paratyphi B, six strains of S. java, 47 strains of S. typhimurium, 24 strains of S. brandenburg, 16 strains of S. derby, nine strains of S. oranienburg, eight strains of S. enteritidis, six strains of S. blockley, five strains of S. heidelberg, four strains of S. typhi, three strains of S. tennessee, three strains of S. onatum, two strains of S. thompson, one strain of S. livingstone, and one strain of S. newport.

The efficacy of each of the selective media used in the study is shown in Tables I-III.

DISCUSSION

From Table I it can be seen that the direct Wilson-Blair plate showed 91 Salmonella strains, 45.5% of all the strains isolated. The direct SS agar plate showed 39 (19.5%) strains; the Müller-Kauffmann enrichment medium 183 (90.5%) strains; the MS enrichment medium 172 strains (86%); the MM enrichment medium 162 strains (81%).

As Table III shows, subculturing on Wilson-Blair agar was much more efficient that on SS agar. Hence, the use of Wilson-Blair agar for subculturing from enrichment media seems strongly indicated. The additional use of SS agar for subculturing is, however, useful, because some strains were isolated on the SS agar but not on the Wilson-Blair agar.

In our hands the Müller-Kauffmann medium was

When also compared, obtained. When also better MM enrichment compared with the salmonellae obtained Iveson, it is efficient only on the medium with Rappaport tetrathionate broth (Difco), as did Rappaport et al. (1956) who used a dehydrated nutrient broth (Difco). According to our experience freshly prepared media from infusion broth usually support the growth of bacteria better than do dehydrated media. It is possible that the Müller-Kauffmann medium is much more efficient when prepared from infusion broth than using a dehydrated medium. It would be well worth examining this possibility.

The MS and MM media are undoubtedly efficient enrichment media. In our laboratory the MS medium gave somewhat better results, but the differences are statistically insignificant. Which of them should be used mainly depends on which medium can be more easily prepared in a given laboratory.

As a rule the MS and MM media should be used only in addition to the standard Müller-Kauffmann medium with a view to increasing the number of positive results. In our material (Table II) the MS and MM media did not greatly increase the number of positive isolations, but in another laboratory if a dehydrated tetrathionate broth were used, the increase of positive results using either the MS or the MM medium might be significant.

We wish to thank Mrs. I. Mamilović, Miss P. Ferbežar, and Mrs. D. Zavodnik for technical assistance.
