
"Clinical Cellular Immunology" is a collection of review articles by different authors. It aims, in the words of its editors, "to create a work combining aspects of cellular immunology with their clinical applications." The great problem which the authors face is that most of the relevant work on cellular immunology has been done in experimental animals. The clinical applications of this work are by no means clear, and few of the chapters bridge the gap between experimental observations and clinical relevance. The first two chapters are very good accounts of current basic immunological concepts.

I suppose it would be difficult to deny that most advances in immunological knowledge have indirect clinical implications, in that understanding is the first step to prevention or cure. But certainly the title of the book made me expect a more clinically orientated work. Even chapters 3 and 4 by Sigel and colleagues on immunosuppressive agents (some 150 pages in the 390 page work) hardly mentions clinical data—there are two and a half pages of glossary to help understand the wealth of experimental information.

The chapter on non-Hodgkin's lymphoma seems particularly poor in defining these conditions in the light of modern knowledge of B cell differentiation—although this is still a somewhat contentious area. Chapter 6 by Burek and his colleagues is a useful reminder of the evidence for the involvement of cell mediated immunity in autoimmune disease, but makes little effort to encourage new perspectives or to indicate the practical consequences of these observations. The chapter on transfer factor is largely theoretical and gives no indication of how clinically useful (or useless) this procedure is. The final chapter on "immunological tests for diagnosis and monitoring of defects in cell mediated immunity" by Fudenberg and colleagues is remarkably sketchy—almost an afterthought.

This book is not recommended for personal purchase, but it may be a useful supplement to a departmental library.

RA THOMPSON

This monograph provides a succinct compendium of the immunofluorescent techniques which have been accepted for routine use in the Public Health Laboratory Service and associated Reference Laboratories. There are short descriptions of equipment, standardisation, and labelling procedures, and a series of sections describing the methods used for detecting different micro-organisms and antibodies. Most of the established reference and routine uses of immunofluorescence are described except, unfortunately, those for the detection of legionella organisms and their antibodies. There is a short comment on interpretation in each section, but the monograph is essentially concerned with techniques which are described with precision and clarity.

This collection of well-tested methods, resulting from the extensive experience of the PHLS will be very welcome. It will provide an authoritative source of methodology and will be valuable to laboratories setting up their own procedures.

PJ SANDERSON

In the small compass of ten chapters Dr Maskell has reviewed the pathogenesis, diagnosis, localisation, natural history, management, and antibiotic treatment of urinary tract infection, has considered the particular problems of such infections in children, and in adults at home and in hospital, and tuberculosis of the urinary tract.

The book is well written and will be appreciated by specialist microbiologists and infectious diseases clinicians, and also by clinicians with a general interest in the subject. That is important because of the significance of UTI in all fields of clinical practice.

The choice of subject matter is necessarily selective but the 240 or so references listed are fairly chosen to present different views. Dr Maskell's own contributions to the subject are, not surprisingly, given prominence with considerable discussion of the importance of micrococci and capphalic organisms as pathogens. Although not all of Dr Maskell's opinions will be accepted by those engaged in research on the subject, that is not a reason for not reading her stimulating book. It should be available in all medical libraries.

RN GRUNEBERG

It is a pleasure to welcome a completely rewritten edition of this laboratory bench book after a long interval. The authors have been assisted by a number of distinguished contributors. The new format is clearly printed and it is easy to find the section one requires; there is a good index.

As before, the well tried colorimetric, nephelometric, and spectrophotometric methods which are quoted in some detail, relate to basic apparatus to be found in reasonably equipped laboratories in any part of the world. Specialists working in more sophisticated laboratories using complex continuous-flow, discrete sampling, and centrifugal analysers, (reference to which is made in this edition) will find that this book still has an important place in their libraries because of the wisdom based on many years of experience expressed in its pages. As a practical training manual it probably has no equal for any person, sci-
Urinary Tract Infection
