Improved immunoturbidimetric method for rheumatoid factor testing

M Nykänen, T Palosuo, K Aho, T Sahi, R von Essen

Abstract
The performance of two immunoturbidimetric modifications for rheumatoid factor (RF) testing, which differ with respect to the means of complement inactivation (heat treatment and inactivation with polyvinyl sulphonate), were compared in serum samples from 87 patients with rheumatoid arthritis (RA) and from 403 healthy subjects. IgM-rheumatoid factor titres were also measured with an enzyme linked immunosorbent assay (ELISA). Both immunoturbidimetric tests gave positive reactions (rheumatoid factor \(>20\) IU/ml) in 74 out of the 87 (85%) RA sera. In cases with high RF concentrations the results after chemical inactivation tended to be slightly higher compared with heat inactivation. In healthy subjects rheumatoid factor was detected in 19/403 (4.7%) sera using heat inactivation and in 22/403 (5.5%) sera with chemical inactivation of complement. Interrun coefficient of variation in the chemical inactivation assay was 4.4%; with the heat inactivation method it was 8.1%. In the ELISA, a marginally better correlation was noted in the results obtained using chemical inactivation.

Inactivation of complement by means of polyvinyl sulphonate offers the advantage of easier test performance and better reproducibility, and the results may reflect more accurately true rheumatoid factor concentrations.

(J Clin Pathol 1993;46:1065–1066)

Several methods for rheumatoid factor (RF) measurement, including nephelometric and turbidimetric assays, have the disadvantage of requiring prior heat inactivation of serum to prevent the binding of complement component C1q to the test antigen. It has been reported that heat inactivation can be avoided by using a chemical inhibitor of C1q, polyvinyl sulphonate. Some serum samples negative after heat inactivation were weakly positive by the new method, but no details for critical assessment of the relevance of this observation were given. As the above may influence the sensitivity and specificity of the assay we decided to study the question further.

Methods
Sera from 87 patients with rheumatoid arthritis (13 men and 74 women) from the Rheumatism Foundation Hospital, Heinola, Finland, were included in the study. Median age of the patients was 60 (range 24–81) years and 67 of them had had rheumatoid arthritis for at least 20 years. Sera from 403 selectively healthy people (331 men and 72 women) working at the Lapland Frontier Guard District comprised a Finnish population sample. Their mean age was 42 (range 19–60) years. All sera were stored as aliquots at \(-70\)°C and had been thawed only once before testing.

ASSAYS FOR RHEUMATOID FACTOR
For immunoturbidimetric measurement of rheumatoid factor, a Kone Specific automated clinical chemistry analyser (Kone Instruments, Espoo, Finland) was used. Immunoturbidimetry using heat inactivation of the sera to destroy complement was performed according to the method of Melamies et al using a commercial kit for rheumatoid factor determination (Orion Diagnostica, Espoo, Finland). Serum specimens were heated at 56 (±)°C to inactivate complement, and aggregated human IgG was used as the antigen for rheumatoid factor, and the reference serum was calibrated against the WHO rheumatoid factor standard. The results were expressed as IU/ml.

Immunoturbidimetry using chemical inactivation of complement was performed essentially as described by Borque et al, except that a different instrument (endpoint turbidimeter instead of a centrifugal analyser) was used. The chemical inactivator of complement was sodium salt of poly(vinyl sulphonic acid), purchased from Aldrich Chemical Company, Milwaukee, Wisconsin, USA, in borate buffer (32 g/l). Reproducibilities of both of the immunoturbidimetric assay modifications were compared by testing one moderate level rheumatoid factor control serum (75 IU/ml) on 21 successive runs. Interrun coefficient of variation (CV) in the chemical inactivation assay was 4.4%, in the heat-inactivation method it was 8.1%.

QUANTIFICATION OF IGM-RF BY ELISA
The method described in detail by Tuomi was used with minor modifications. Briefly, polystyrene microtitre plates (Immunoplate I, Nunc, Roskilde, Denmark) were coated with purified Fc fragments of human IgG (2.5 \(\mu\)g/ml; Jackson Immunoresearch Laboratories, West Grove, Philadelphia) and IgM-RF bound from the test sera was detected by alkaline phosphatase conjugated F(ab')\(_2\)-fragment of Fc \(\mu\)-specific anti-human IgM (Jackson Immunoresearch). The colour formed in reaction with p-nitrophenyl-phosphate was read in a Titertek Multiskan spectrophotometer (Eflab, Helsinki, Finland). Rheumatoid factor standard serum diluted to contain 15-25, 30-5, 61 and 122 IU/ml was included in each plate and the optical density values for each serum were converted to IU/ml. All determinations were done in duplicate. Interrun (n = 38) CV at low to moderate rheumatoid factor concentration was 9.5%.

Results

Positive rheumatoid factor test results (≥20 IU/ml) were recorded in 74/87 (85%) rheumatoid arthritis sera by both immunoturbidimetric assays. Among the selectively healthy subjects immunoturbidimetry using heat inactivation of complement gave positive results in 19/403 (4.7%) sera while chemical inactivation demonstrated rheumatoid factor in 22/403 (5.5%) sera. IgM-RF ELISA gave positive results in 86% of the rheumatoid arthritis sera and in 5.5% of the control sera.

There was in rheumatoid arthritis sera a good correlation between the results by the two immunoturbidimetric assays (table and figure). In sera with rheumatoid factor concentrations above 100 IU/ml the results when using chemical inactivation tended to be slightly higher. No corresponding phenomenon was seen in sera with rheumatoid factor concentrations below 100 IU/ml. In all control sera the rheumatoid factor concentrations, as measured by the two immunoturbidimetric assays, were below 100 IU/ml, and both higher and lower test results were recorded when using chemical inactivation (figure). There was only a modest correlation in the control sera between the two assays (table).

The correlations between the results by the two immunoturbidimetric assays were better than those between IgM-RF ELISA and each of the immunoturbidimetric assays (table). Both in rheumatoid arthritis sera and in control sera a marginally better correlation was noted between IgM-RF ELISA and immunoturbidimetric assay using chemical inactivation of Clq compared with the assay using heat inactivation.

Discussion

Our observations agree with earlier findings showing a good correlation between the results of the immunoturbidimetric rheumatoid factor assays using heat inactivation and chemical inactivation of Clq. Yet in sera with high rheumatoid factor concentrations the results by the latter modification tended to be slightly higher. This may be due to binding of rheumatoid factor to autologous aggregated IgG induced by heat treatment or, perhaps more likely, to a direct inactivation of some rheumatoid factor moieties due to this procedure. For some reason, a corresponding trend was not observed in sera with lower rheumatoid factor concentrations. There was no appreciable difference between the two modifications in the frequency of positive reactions either in rheumatoid arthritis sera or in control sera.

The correlation between the two immunoturbidimetric modifications was poor in sera with rheumatoid factor concentrations below 20 IU/ml (figure). We have already shown that correlations in non-rheumatoid sera between immunoturbidimetric assay, latex slide test, and IgM-RF ELISA were also poor when rheumatoid factor concentrations were below 20 IU/ml. Marginally better correlation was observed in the present series between IgM-RF ELISA and immunoturbidimetric assay after chemical inactivation of Clq than after heat-inactivation both in rheumatoid arthritis sera and in control sera. Thus addition of polyvinyl sulphonate to the reagent buffer offers the advantage of easier performance of immunoturbidimetric testing. Results obtained by this modification may reflect more accurately true rheumatoid concentrations, and sensitivity and specificity of the assay remain essentially the same.

Improved immunoturbidimetric method for rheumatoid factor testing.
