Papillary mucinous adenoma arising in adenomyomatous hyperplasia of the gall bladder

G Y Lauwers, S J Wahl, G V Scott, S J DeRoux

Abstract
A case of papillary mucinous adenoma arising in adenomyomatous hyperplasia (AMH) of the gall bladder is reported. The lesion was unsuspected and discovered by routine palpation of the gall bladder during laparotomy. The adenoma developed within fundal AMH and showed cytological atypia. This case illustrates that neoplastic proliferation is indeed possible in AMH and challenges the classical opinion that AMH is devoid of neoplastic potential.

Methods
Sections of the gall bladder were fixed in 10% buffered formalin and embedded in paraffin wax. Paraffin wax sections 4 μm thick were stained with haematoxylin phloxine saffron. Histochemical stains including periodic acid Schiff (PAS), with and without diastase pre-treatment, mucicarmine, and alcin blue were applied to the sections. Sections were also stained immunohistochemically with chromogranin (Boehringer Mannheim, Indianapolis, Indiana, USA) monoclonal antibodies using the avidin-biotin peroxidase technique, as described previously.

Results
Pathological Findings
On gross examination, the fundus of the acalculous gall bladder showed a dome shaped, cystic lesion measuring 2 x 1.3 x 1 cm. Microscopically, the gall bladder mucosa showed normal luminal folds lined by a single layer of columnar epithelium. The stroma was slightly fibrotic and contained lymphocytes in small clusters. AMH was identified within the wall of the fundus as the typical multiple anastomosing, epithelium lined extrusions extending between bundles of hyperplastic smooth muscle. Foveolar type mucinous metaplasia of the hyperplastic epithelium was also present. A large cyst measuring 11 x 5 mm was observed in continuity with AMH. Its lining was composed of tall mucinous cells with focal formation of papillae (figs 1 and 2). A large villous polyoid lesion formed of anastomosing fronds protruded into the cystic space. The fibrovascular stroma of the papillae was infiltrated by lymphocytes and plasma cells. Most of the fronds were lined by a single layer of benign mucus cells, although focal cellular tufting and nuclear atypia were present.

Case report
An 86 year old woman was admitted for surgery following a diagnosis of adenocarcinoma of the left colon. A preoperative workup showed no evidence of metastatic tumour and a left hemicolectomy was performed. At surgery, palpation of the gall bladder revealed a small soft mass at the tip of the fundus and a cholecystectomy was performed. The postoperative course was uneventful and the patient is alive and well 17 months after surgery.
to the surface epithelium of the gall bladder, the foveolar type metaplastic epithelium of the AMH and the adenoma lacked acid mucins but were positive for neutral mucin. The histological and histochemical similarity support the conclusion that the papillary mucinous adenoma arose from the AMH. To the best of our knowledge, the present case is the first detailed description of such neoplastic change arising within AMH. In 1982, Von Matting et al. described a so-called “benign papillary cystadenoma of the gall bladder fundus”, suggesting a similar lesion, but their report did not contain a precise microscopic description. AMH, regarded as a hyperplastic lesion, combines excessive surface epithelial proliferation with exudation of the mucosa through a thickened muscular wall. This acquired process can be diffuse, segmental, or localised with a propensity for the fundus. Its frequency has been reported to vary between 2 and 25% in both surgical and radiological retrospective studies. More commonly recognised in women, its incidence increases with age. Although most lesions are asymptomatic, non-specific cholecystitis-like symptoms have been reported. Cyst formation secondary to inflammation, fibrosis, and inspissated bile has also been described. Abscess formation has been the most frequently reported complication.

The association between AMH and gall bladder cancer is unclear. Although regarded classically as a benign process, recent publications have challenged this opinion. Ootani et al. redefined the association between AMH and gall bladder cancer. In their series 11.4% of gall bladder cancers developed in the fundal compartment, distal to the stricture induced by AMH. They suggested that segmental AMH was a causative factor in gall bladder cancer, but indicated that this relation was not true for diffuse or fundal AMH. Of more interest in the light of the case reported here are the eight cases of gall bladder cancer which developed directly in AMH. The following are of particular relevance: four of the eight gall bladder cancers developed in localised AMH of the fundus; mucinous metaplasia was present in two of these four cases; and in one case the carcinoma arose from a papillary adenoma similar to the case presented in this report.

The case presented here, supported by the recent reports of gall bladder cancer arising in AMH, suggests that AMH may have neoplastic potential. In some cases at least an adenoma could be one of the intermediate steps in the carcinogenic sequence. The possibility that mucinous metaplasia in AMH is indicative of a predisposition to neoplasia requires investigation. That the histological features of our case are reminiscent of the mucinous cystadenoma of the appendix is of particular interest.

The clinical significance of our finding is limited at present. AMH is a frequent finding during surgery and has an excessively low malignant potential (if any greater than normal epithelium). None the less, awareness of the possibility of malignant degeneration might be
Induction of interleukin-8 secretion from gastric epithelial cells by a \textit{cagA} negative isogenic mutant of \textit{Helicobacter pylori}

J E Crabtree, Z Xiang, I J D Lindley, D S Tompkins, R Rappuoli, A Covacci

Abstract
The ability of \textit{Helicobacter pylori} strains to induce interleukin-8 (IL-8) gene expression and protein secretion from gastric epithelial cell lines in vitro is variable. This cellular response is associated with bacterial expression of the \textit{CagA} protein present in type \textit{I H pylori} strains. To determine the role of \textit{CagA} in this host cell response, an isogenic \textit{cagA} negative mutant, N6.XA3, was constructed. The \textit{cagA} negative isogenic mutant and the wild-type parental \textit{cagA} positive strain, N6, were co-cultured with AGS, ST-42 and KATO-3 gastric epithelial cell lines and secreted interleukin-8 assayed by enzyme linked immunosorbent assay. In all three cell lines there was no significant difference in the IL-8 secretion induced by the \textit{cagA} negative isogenic mutant, N6.XA3, and the wild-type parent strain, N6. These studies show that \textit{CagA} is not the inducer of IL-8 secretion from gastric epithelial cells. As all wild-type \textit{CagA} positive strains studied to date induce IL-8, the bacterial factor(s) inducing this inflammatory response is closely associated with the expression of \textit{CagA}.

(Keywords: Interleukin-8, \textit{Helicobacter pylori}, \textit{CagA}, epithelial cells, gastritis.)

The \textit{CagA} surface protein of \textit{Helicobacter pylori} is highly immunogenic and is expressed in about 60 to 70% of \textit{H pylori} strains. Mucosal IgA antibody recognition of this protein has been linked with peptic ulcer disease and the activity of gastritis and systemic IgG responses to \textit{CagA} are also elevated in ulceration. Strains of \textit{H pylori} which have the gene coding for \textit{CagA} and express this immunogenic protein usually coexpress the vacuolating cytotoxin (VacA). Strains with this genotype/phenotype have recently been classified as type I bacteria. Type II strains lack the \textit{cagA} gene and express neither the \textit{CagA} protein nor the VacA protein. While the VacA protein is thought to be an important mediator of gastric mucosal damage, this protein does not elicit gastric inflammatory cell infiltration in animal models. 

Papillary mucinous adenoma arising in adenomyomatous hyperplasia of the gall bladder.
