Letters

Workload measurement in histopathology

I am surprised that both Suvarna and Kay’s paper on workload measurement in histopathology and Furness’ subsequent commentary do not refer to North American reports on this subject. A formal method of assessing physician workload and value has been developed in the USA from 1988 onwards and is now in widespread use for billing.

The basis of the system has been published in detail. The system uses a relative value unit (RVU) for comparing the “physician value” of different activities. The value includes: time taken; mental effort and judgement; technical skill and physical effort; and psychological stress. Relative values are assigned to a service by asking a sample of practitioners to rate the value of the service in relation to a reference service. It has been shown to be reproducible and valid. Relative value scales have been developed for pathology and are published in the Federal Register. The services and procedures are defined in the American Medical Association’s Current procedural terminology.

As an illustration, using the limited published data on individual workload and making reasonable assumptions, an efficient whole time equivalent pathologist working 44 weeks a year, seven laboratory sessions a week (three sessions for meetings, audit, management and research) might “earn” about 4500 RVUs per annum.

This equates to:

<table>
<thead>
<tr>
<th>Type of Service</th>
<th>RVU</th>
</tr>
</thead>
<tbody>
<tr>
<td>4286 FNAs</td>
<td>10 714 pathologist interpretations of cervical cytology</td>
</tr>
<tr>
<td>1974 large resections, for example bowel, prostate, or lung for neoplasm</td>
<td>6000 biopsy specimens of colon, stomach, or prostate</td>
</tr>
<tr>
<td>20 455 appendices or gallbladders</td>
<td>34 615 vas or fallopian tubes from sterilisations</td>
</tr>
</tbody>
</table>

[Note: the unit of service is the specimen and extra credit is given for special stains.]

Accurate measurement of workload is important to determine departmental resources, for internal departmental allocation of work, and to assess the likely impact of service developments. It may become even more important in the near future when the manpower planning failures of the last few years lead to short staffed departments and gross discrepancies between individual workloads. This situation will doubtless lead to demands for redistribution of work and/or remuneration; these potential disputes can only be solved fairly if there is an accepted way of measuring workload.

The RVU system seems fair and should be easy to apply and to audit. It is consistent, has been validated, and is under regular review. There is every good reason to introduce it to the United Kingdom as a way of measuring workload in histology and cytopathology.

Chlamydia pneumoniae and atherosclerosis

In their leader article, Taylor-Robinson and Thomas cogently discussed the association of C. pneumoniae and atherosclerosis and examined whether C. pneumoniae infection is specific for arteries and atheroma. We agree that current evidence suggests that it is not. In a recent review, C. pneumoniae has been associated with several diseases, among which the only common factor seems to be the presence of diseased tissue (table). The authors also discussed how future studies should be designed to investigate its role in atherosclerosis. We agree that although pathological studies have demonstrated the presence of C. pneumoniae in atherosclerotic vessels, they can never show whether infection causes or follows its development. Animal studies and antibiotic intervention trials are therefore required to prove that C. pneumoniae is clinically important. However, the concern is that some populations that are prevalent of chronic active C. pneumoniae infection may be too low to enable unselective trials to show an effect where in fact one may exist. Furthermore, for reasons of appropriate prescribing alone, antibiotics should only be given to subjects in whom there is good reason to believe there is current C. pneumoniae infection, especially if, as has been suggested, treatment may need to be for prolonged periods of up to a year. Future research should therefore include efforts to determine how infected individuals can be rapidly identified. We believe serology is inadequate. Specific tests of current infection, such as probing for C. pneumoniae DNA in blood or monocytes need urgently to be validated.

Authors’ response

Wong and Ward concur with the major points we made in highlighting the efforts that are required to unravel the role of Chlamydia pneumoniae in atherosclerosis. Their comments, however, go beyond this and focus on a possible association of C pneumoniae with some other diseases. Despite the occasional voice of dissent, there is now overwhelming evidence of an association between C pneumoniae and atherosclerosis. What this means is quite unclear and is, of course, the overriding question that needs to be resolved. Many would think an association of C pneumoniae with asthma1 and to a lesser extent with sarcoidosis2 is a reasonable proposition. However, as the microorganism is to be found in peripheral blood mononuclear cells of a substantial proportion of individuals with and without cardiovascular disease,3 it is possible for it to lodge just about anywhere in the body and all sorts of relations with disease might be imagined, many perhaps turning out to be spurious. Indeed, it is reasonable to list rheumatoid arthritis and Alzheimer dementia in the same context as atherosclerosis? We think not. There is some evidence, which certainly needs to be substantiated, for an association between C pneumoniae and the HLA-B27 positive spondyloarthropathy subgroup of juvenile chronic arthritis,4 but we are aware of only a single report of C pneumoniae in one adult with rheumatoid arthritis.5 Furthermore, while there is a report of this microorganism being found in brain tissue of patients with Alzheimer disease,6 is a single, unconfirmed report sufficient to talk in terms of an association that means anything? While it is feasible, it would, nevertheless, be startling if future research showed that this single microorganism was responsible for so many diverse diseases.

PCR to detect M tuberculosis

Although aspirates from solitary pulmonary nodules were not included among specimens used to assess the rapid polymerase chain reaction (PCR) technique,1 this technique shows promise in improving the diagnostic rate for M tuberculosis in solitary pulmonary nodules of < 4 cm diameter.2 Seven of eight asirates from patients with other evidence of tuberculosis (including five with bacteriological proof, and three with a significant response to a therapeutic trial of chemotherapy) tested positive by PCR, and one of three not validated by either technique also tested positive by PCR.3 The sensitivity of PCR for aspirates from solitary pulmonary nodules is therefore impressively high, with virtually no false positives. The clinical decision process for malignant solitary pulmonary nodules which at present generates a positive predictive value of the order of a mere 50%, thereby yielding an unacceptably high resection rate for benign (including tuberculous) lesions,4 would be greatly enhanced by a more enthusiastic use of the PCR technique.

Notice

International Society of Dermatopathology: 20th Colloquium  
24–26 September 1999  
Prague

“Dermatopathology and General Pathology are One Pathology”

Co-sponsored by the European Society of Dermatopathology and the Dermatopathology Group of the Czech Dermatological Society. The Colloquium includes a long course, a short course, a self-assessment course, free communications, poster sessions, and breakfasts with leading dermatopathologists from different parts of the world.

Further details from: Dr Jana Hercogova, Charles University 2nd Medical School, Department of Dermatology, V uvalí 84, 150 18 Prague 5, Czech Republic; tel +420 2243 8700; fax +420 2243 8720; email: jana.hercogova@ffn.muni.cz

Corrections

In the leader by Dobkins, Kite and Wilcox in the March issue (vol 52, page 169) there is an uncorrected error in the section headed “Acridine orange staining of catheter blood.” Line 4 of this section should read: “The technique requires as little as 50 µl of blood...”

In the leader by McMullin in the April issue (vol 52, page 247), a single sentence has been separated unintentionally into two. In the left hand column, three lines from the bottom of the page, the sentence as corrected should read: “As the gene is on the X chromosome and the other X chromosome is “ lyonised” in females, leading to inactivation of the lyonised gene, damage to a single gene results in abnormal GPI anchor expression.”
Instructions for Authors

Papers for publication should be sent to the Editor, Journal of Clinical Pathology, BMA House, Tavistock Square, London WC1H 9JR (tel: 0171 383 6209/6154; fax: 0171 383 6668; email: jclinpathol@compuserve.com). Receipt of manuscripts will be acknowledged by the editorial office. Submission of a paper will be held to imply that it contains original work not being offered elsewhere or published previously. Manuscripts should be prepared in accordance with the Vancouver style. The Editor retains the right to shorten the article or make changes to conform with style and to improve clarity. All authors must sign the copyright form after acceptance.

Failure to adhere to any of these instructions may result in delay in processing the manuscript and it may be returned to the authors for correction before being submitted to a referee.

General
- Authors must submit four copies of the original manuscript typed in double line spacing. The journal is now produced electronically and revised manuscripts should be submitted as printed copy and on disk. A guide to submitting an article on disk will be sent when requesting a revision or notification of an acceptance. Authors should not submit the original paper on disk.
- The names of the authors, with initials, should be followed by the name of the institution where the work was carried out. An indication of the position held by each author should be given in an accompanying letter to the Editor, and manuscripts should bear the name of one author to whom correspondence should be addressed. If available, a fax number and an email address should be supplied.
- Identifying information should not be published in written descriptions, photographs, or pedigrees unless the information is essential for scientific purposes and the patient (or parent or guardian) gives written informed consent for publication; but patient data should never be altered or falsified in an attempt to attain anonymity. Informed consent should be obtained if there is any doubt. Masking the eyes in photographs of patients is insufficient protection of anonymity (for the full statement see the BMJ).
- Authors should include the names and addresses of four experts whom the authors consider suitable to peer review their work.
- When submitting original manuscripts authors should send a copy of any of their other papers on a similar subject to assure the editors that there is no risk of duplicate publication.
- If requested, authors should produce the data upon which the manuscript is based for examination by the Editor.
- The number of authors should be kept to a minimum and should include only those who have made a contribution to the research: justification should be made for more than five authors. Acknowledgments should be limited to work, whose contribution or assistance has extended beyond their paid work, and to supporting organisations.
- Sponsors of research must be declared.
- Authors should provide up to four keywords/phrases for the index.
- All measurements must be in SI units apart from blood pressure measurements, which should be in mm Hg, and drugs in metric units.
- Abbreviations should be used rarely and should be preceded by the words in full before the first appearance.
- In the statistical analysis of data 95% confidence intervals should be used wherever appropriate.
- Any article may be submitted to outside peer review and for statistical assessment.
- No free offprints will be provided; reprints may be ordered when the paper is returned.

Original articles
- Papers should be no more than 2000 words long and should report original research of relevance and understanding and practice of clinical pathology. They should be written in the standard form: abstract; introduction; methods; results; and discussion.
- The journal uses a structured form of abstract in the interests of clarity. This should be short (no more than 250 words) and include four headings: Aims—the main purpose of the study; Methods—what was done, and with what material; Results—the most important results illustrated by numerical data but not p values; and Conclusions—the implications and relevance of the results.

Leaders/Editorials
- Leaders and Editorials are published by editorial invitation and reviews on topical themes and commentaries are unlikely to be accepted, though the Editor is always pleased to receive suggestions.

Short reports
- Single case reports of outstanding interest or clinical relevance, short technical notes, and brief investigations are welcomed and usually published in the form of a Short/Technical report.
- Length must not exceed 1500 words, including an unstructured abstract of less than 150 words, up to two figures or tables (or one of each) and up to 10 references. If more illustrations are required the text must be reduced accordingly.

Letters
- Letters must be typed in double line spacing, should not exceed 1000 words, have no more than five references, and must be signed by all authors. Two copies should be provided.

Tables and illustrations
- Tables should be presented separately in double line spacing without ruled lines; when presented on disk they should be in a separate file from the text.
- Letters and other marks which are to appear on the face of a photograph should be made on a photocopysticker that will be added in the Journal style in the editorial office when the manuscript is accepted.
- Legends for illustrations should be typed with double spacing on a separate sheet. The staining technique used should be stated. Magnifications should be given for electron micrographs but not for light micrographs except in cases where this is important.
- Photographs and photomicrographs should be on glossy paper for half tone reproduction. The printing process requires that prints are unmounted and backed, and of high quality, with full tonal scale. Illustrations that will not reproduce well will be returned and this may delay publication. Areas in which tissue does not appear (“background”) should be as near white as possible. Three sets of prints must be supplied with each manuscript. Only salient features should be included to preserve detail.
- Colour reproduction of figures in papers is encouraged and is heavily subsidised by the Journal. Advice on costs and material to be submitted for colour work should be sought from the editorial office. The journal can accept colour images as TIFF files in the following media: zipped or unzipped files on floppy disks, compact disks, or optical disks. A hard copy of the image should be provided.
- If any tables or illustrations submitted have been published elsewhere, written consent to republication should be obtained by the author from the copyright holder (usually the publisher) and the authors. A copy of the letter giving consent must be included.

Descriptions of laboratory methods
- When a manufacturer’s method is used in a study with a particular item of equipment or kit of reagents, the source of this method and reference to the scientific literature on which it was based should be given. Authors might consider it courteous to inform manufacturers that an article assessing their product has been submitted for publication. For quantitative methods, information on the sensitivity, precision, and accuracy in the hands of the authors should always be provided. When a well recognised method is used, these requirements could be met simply by providing the references to the methodology and discussing the performance in a recognised current quality assurance scheme. Modifications to methods that have not been previously published should be detailed in the text and supported by evidence of their efficacy.
- It is useful to indicate, either from personal observations or by reference, the working range of an assay and the normal reference range when it is used on samples from humans. When information is expressed as mean ± 2SD, the distribution of the range (normal, skew, or logarithmic) should be stated.

References
- References must be numbered in the order they appear in the text and include all information (Vancouver style; references with more than three authors should give only the first three followed by et al): 1 Fletcher CDM, McKee H. Sarcomas - a clinicopathological guide with pathological manifestations. I. Dermatofibrosarcoma protuberenans, malignant fibrous histiocytoma and the epithelial sarcoma. Exs 1984;9:451–65. 2 Washington JA. Conventional approaches to blood culture. In: Washington JA, ed. The detection of septicemia. West Palm Beach, Florida: CRC Press, 1978:41–87. 3 References in the text should be identified by arabic numerals in brackets—for example, [1] [2]. 4 Information from manuscripts not yet accepted, or personal communications may be cited only in the text and not included in the references if they are not checked by us; authors must verify references against the original documents before submitting the article. 5 International Committee of Medical Journal Editors. Uniform requirements for manuscripts submitted to biomedical journals. BMJ 1991;302:38–41. 6 International Committee of Medical Journal Editors. Protection of patients’ rights to privacy. BMJ 1995;311:1272.

Manuscript checklist:
- Is there an abstract?
- Are the abbreviations spelt out?
- Are the measurements in SI units?
- Are the references in Vancouver style?
Chlamydia pneumoniae and atherosclerosis.
