Inhibin is more specific than calretinin as an immunohistochemical marker for differentiating sarcomatoid granulosa cell tumour of the ovary from other spindle cell neoplasms

V I Shah, O N Freites, P Maxwell, W G McCluggage

Aims: To describe a case of a recurrent sarcomatoid adult granulosa cell tumour (AGCT) of the ovary and to evaluate the usefulness of two ovarian sex cord stromal markers (inhibin and calretinin) in separating sarcomatoid AGCT from true sarcomas.

Methods: A 72 year old woman presented with a recurrent sarcomatoid AGCT in the sigmoid colon mesentery, which histologically mimicked a malignant gastrointestinal stromal tumour (GIST). This index case and 79 sarcomas (32 GISTs, 28 leiomyosarcomas, 15 endometrial stromal sarcomas (ESSs), including one with sex cord-like areas, and four undifferentiated uterine sarcomas) were immunostained using antibodies to inhibin and calretinin.

Results: The recurrent sarcomatoid AGCT expressed diffuse, strong cytoplasmic immunoreactivity with inhibin and focal but strong nuclear and cytoplasmic positivity with calretinin. Focal, weak cytoplasmic inhibin expression limited to sex cord-like areas was present in one ESS. None of the other sarcomas expressed inhibin. Focal, strong calretinin immunoreactivity was identified in 11 leiomyosarcomas and one GIST. The case of ESS with sex cord-like areas showed strong immunoreactivity for calretinin limited to the sex cord-like areas.

Conclusions: Inhibin is a useful immunomarker to distinguish sarcomatoid AGCT from other spindle cell neoplasms that may enter into the differential diagnosis. Calretinin appears to be less specific than inhibin.

In our study, we describe a case of a recurrent sarcomatoid AGCT that clinically mimicked a primary colonic tumour and histologically was suggestive of a malignant gastrointestinal stromal tumour (GIST), and evaluate the usefulness of antibodies against inhibin and calretinin in differentiating sarcomatoid AGCT from various sarcomas.

Abbreviations: AGCT, adult granulosa cell tumour; GIST, gastrointestinal stromal tumour; ESS, endometrial stromal sarcoma

MATERIALS AND METHODS

Index case

A 72 year old woman had a sarcomatoid AGCT of the left ovary resected followed by treatment with two courses of platinum based chemotherapy and radiotherapy. She represented four years later with a large mass in the sigmoid colon mesentery, which was clinically and radiologically felt to be a primary colonic tumour. A segmental resection of the sigmoid colon revealed a 9 × 8 × 4 cm necrotic grey/white soft tumour in the mesentery. Initial histological examination revealed a predominantly sarcomatoid tumour with moderate nuclear pleomorphism, brisk mitotic activity (eight to nine mitoses/10 high power fields) and foci of necrosis, reminiscent of a malignant GIST (fig 1A). In view of the clinical history of an AGCT of the ovary, further sections were examined and these revealed focal areas of insular, ribbon-like, cystic and follicular patterns with some nuclear grooving (fig 1B). These typical areas were very sparse and were found only after extensive sampling. The histological appearances

Calretinin, a 29 kDa calcium binding protein best known for its role in the diagnosis of mesothelioma, has also been suggested as an immunohistochemical marker for ovarian sex cord-stromal tumours. However, calretinin positivity has been demonstrated in a small number of benign spindle cell neoplasms and sarcomas.

“Sarcomatoid adult granulosa cell tumour may be misinterpreted as a sarcoma, particularly when it recurs at a site distant from the ovary, and the pathologist is unaware of the history of a primary ovarian tumour in the distant past”
in conjunction with the immunostaining results (discussed below) were interpreted as recurrent sarcomatoid AGCT.

**Specimens**

Formalin fixed, paraffin wax embedded blocks of 79 sarcomas (32 GISTs, 28 leiomyosarcomas (20 uterine, two retroperitoneal, two colonic, one urinary bladder, and one larynx), 15 endometrial stromal sarcomas (one with sex cord-like areas), and four undifferentiated uterine sarcomas) were retrieved from the histology files of the departments of pathology, Swansea NHS Trust and Royal Group of Hospitals Trust, Belfast. The histological diagnosis was confirmed by review of haematoxylin and eosin stained sections and representative blocks were selected for immunohistochemistry.

**Immunohistochemical staining**

Sections were cut on to coated slides (Sigma, Poole, Dorset, UK) and dried overnight at 37°C. Endogenous peroxidase activity was blocked by 3% alcoholic hydrogen peroxide for 10 minutes. Sections were pretreated in an 850 W domestic microwave oven in citrate buffer (pH 6.0) for 20 minutes and allowed to cool for 20 minutes. Sections were incubated for 60 minutes with mouse monoclonal antibody to human inhibin (Serotec, Oxford, UK) and with polyclonal anticalretinin (1/50 dilution; Zymed, San Francisco, California, USA). Localisation was performed using Envision peroxidase (Dako, Ely, Cambridgeshire, UK). Diaminobenzidine (Dako) was used as the chromogen.

Negative controls, where the primary antiserum was omitted and replaced with mouse or rabbit immunoglobulin (Dako), were included. Positive controls for each antibody were also included. These comprised ovaries containing follicular cysts for anti-inhibin and a mesothelioma with known immunoreactivity for anticalretinin.

**RESULTS**

**Index case**

The tumour cells showed diffuse, strong cytoplasmic immunoreactivity with antibodies against vimentin and inhibin (fig 1C), focal, strong, membranous positivity with pancytokeratin specific antibody, and focal, strong, nuclear and cytoplasmic positivity with the antibody to calretinin (fig 1D). There was no expression of epithelial membrane antigen, α smooth muscle actin, desmin, HHF-35, or CD34.

**Sarcomas**

Thirteen cases (one GIST, 11 leiomyosarcomas (seven uterine; one each of colon, skin, retroperitoneum, and urinary bladder) and one endometrial stromal sarcoma (ESS) with sex cord-like areas) showed moderate to strong, focal (< 25% tumour cells) cytoplasmic and nuclear staining for calretinin, with the immunoreactivity in ESS limited to sex cord-like areas (fig 2). All sarcomas were immunonegative for inhibin except for one case of ESS, which showed focal, weak cytoplasmic immunoreactivity limited to the associated sex cord-like areas.

**DISCUSSION**

The sarcomatoid variant of an ovarian AGCT may mimic a variety of sarcomas. Flemming et al reported three cases of metastatic sarcomatoid AGCT (two in the liver and one in the left abdominal region) that had been misinterpreted as haemangiopericytoma or leiomyosarcoma by several pathologists.5 Our index case of recurrent sarcomatoid AGCT in the sigmoid colon mesentery resembled a primary colonic tumour clinically and radiologically, and a malignant GIST by routine histology.

In general, immunohistochemical staining with antibodies against epithelial and mesenchymal antigens is of little value.
in differentiating sarcomatoid AGCT from genuine sarcomas because none of the other sarcomas tested expressed inhibin, except for one endometrial stromal sarcoma (ESS), which showed focal, weak cytoplasmic inhibin expression limited to sex cord-like areas. However, there is little information in the literature regarding inhibin and calretinin staining in extraovarian neoplasms that may mimic sarcomatoid AGCT. In our study, all the 79 sarcomas lacked immunoreactivity for inhibin except for one case of ESS that showed focal, weak positivity limited to associated sex cord-like areas. Inhibin positivity in the sex cord-like areas of ESS has been described previously, and would suggest that these areas represent true sex cord differentiation in ESS.5–7 Our results are also similar to those of Flemming et al, who found no expression of inhibin in the small number of sarcomas (three haemangiopericytomas and four leiomyomatous tumours) studied.5 Thus, inhibin immunoreactivity in a spindle cell neoplasm should suggest sarcomatoid AGCT.

It has been suggested that calretinin is a slightly more sensitive marker than inhibin for ovarian sex cord stromal tumours.9 However, in our experience, calretinin is less specific because 13 of 79 sarcomas expressed calretinin. There are conflicting data in the literature regarding calretinin expression in spindle cell neoplasms. In the study by Attanoos et al none of the 30 spindle cell neoplasms expressed calretinin,18 but other studies have reported calretinin expression in a variety of spindle cell neoplasms, including synovial sarcoma, malignant peripheral nerve sheath tumour, solitary fibrous tumour, and cardiac myxoma.10–14 Hence, calretinin positivity in spindle cell neoplasms must be interpreted with caution.

In summary, we conclude that inhibin is a useful immunohistochemical marker to distinguish sarcomatoid adult granulosa cell tumour from other spindle cell neoplasms because none of the other sarcomas tested expressed inhibin, except for one endometrial stromal sarcoma (ESS), which showed focal, weak cytoplasmic inhibin expression limited to sex cord-like areas. Calretinin appears to be less specific than inhibin because focal, strong calretinin immunoreactivity was identified in 11 leiomyosarcomas and one gastrointestinal stromal tumour. In addition, the case of ESS with sex cord-like areas showed strong immunoreactivity for calretinin limited to the sex cord-like areas.

NOTE IN EDITING
Since the submission of this paper, Movhedi-Lankarani and Kurman have reported a comparison of calretinin and inhibin immunostaining in 215 ovarian tumours. They concluded that calretinin is a more sensitive but less specific marker than inhibin for ovarian sex cord stromal neoplasms.19

ACKNOWLEDGEMENT
We thank Dr RB Denholm, Department of Pathology, Carmarthen and District NHS Trust for providing the slides of the primary ovarian AGCT for review.

Take home messages
- Inhibin is useful as an immunomarker to distinguish sarcomatoid adult granulosa cell tumour from other spindle cell neoplasms because none of the other sarcomas tested expressed inhibin, except for one endometrial stromal sarcoma (ESS), which showed focal, weak cytoplasmic inhibin expression limited to sex cord-like areas.
- Calretinin appears to be less specific than inhibin because focal, strong calretinin immunoreactivity was identified in 11 leiomyosarcomas and one gastrointestinal stromal tumour. In addition, the case of ESS with sex cord-like areas showed strong immunoreactivity for calretinin limited to the sex cord-like areas.

Because the diagnosis of AGCT has important therapeutic implications, the immunomarkers used for the differentiation of sarcomatoid AGCT from genuine sarcomas should be specific. Both inhibin and calretinin have been shown to be sensitive markers of AGCT. In our experience, calretinin is less specific because focal, strong calretinin immunoreactivity was identified in 11 leiomyosarcomas and one gastrointestinal stromal tumour. In addition, the case of ESS with sex cord-like areas showed strong immunoreactivity for calretinin limited to the sex cord-like areas.
