International enzyme units and isoenzyme nomenclature

At the present time enzyme activities are expressed in many widely different terms, and comparisons of the activity of two enzymes or of two methods for the same enzyme is often difficult or even impossible. In an attempt to overcome this confusion the Clinical Enzyme Subcommission of the International Union of Biochemistry and the Biological Section of the International Union of Pure and Applied Chemistry has agreed, in conformity with the recommendations contained in the Report of the Commission on Enzymes of the International Union of Biochemistry (1961), to encourage the expression of all activities in terms of international units, defined as micromoles of substrate transformed per minute under defined conditions, preferably optimal. Concentrations are best expressed in units per litre or units per millilitre, depending on which gives the more convenient figure for the particular enzyme. These units are only standard as long as the conditions defining them are strictly adhered to during enzyme assay: if, for example, the temperature of incubation were to change, the apparent activity of the enzyme preparation would also change. It is therefore still essential to specify the method of estimation that has been used.

When alternative assay procedures using different substrates exist for a particular enzyme, e.g., serum alkaline phosphatase, dissimilar values will result, unless the rate of action of the enzyme on each substrate happens to be equal. By expressing activities in international units, a direct comparison can be made of the relative rates at which an enzyme acts on different substrates.

For enzymes such as hyaluronidase, whose activity is not easily expressed in precise chemical terms, an arbitrary standard preparation may be necessary. The activity of certain digestive enzymes cannot readily be converted into micromoles of substrate split or of products formed: the assay of serum amylase by a decrease in the blue colour given by iodine with a starch substrate in a known time is an example of this situation. It is often possible, however, to calibrate such methods against ones in which the reaction can be expressed in international units.

Examples of calculations for the conversion of conventional to international units

**Alkaline phosphatase.** A King-Armstrong unit is defined as the amount of the enzyme that will set free 1 mg. of phenol in 15 min. under the conditions of the test, and hence units = mg. of phenol set free by hydrolysis from phenyl phosphate.

Since 1 K.A. unit = 1 mg. phenol per 15 min.

\[ = 1,000 \mu\text{g. phenol per 15 min.} \]

\[ = \frac{1000}{94} \mu\text{moles phenol per 15 min.} \]

\[ = 0.071 \mu\text{moles/min.} \]

\[ = 1 \text{ K.A. unit/100 ml.} \]

\[ = \frac{1}{10} \mu\text{moles/min. of alkaline phenylphosphatase activity per litre; and the commonly accepted range of normal values of 3 to 13 K.A. units/100 ml. corresponds to about 20 to 90 \mu\text{moles/min./litre.} \]

One Bodansky unit of alkaline phosphatase = 1 mg. inorganic P hydrolysed in one hour from \( \beta \)-glycerophosphate. Since the atomic weight of P is 31,

\[ 1 \text{ Bodansky unit } = \frac{1}{31} \text{ moles/min.} \]

\[ = 0.0535 \mu\text{moles/min.} \]

\[ = 1 \text{ Bodansky unit/100 ml.} \]

\[ = \frac{0.0535}{10} \mu\text{moles/min. of \( \beta \)-glycerophosphate activity per litre; and the normal range of 1 to 5 Bodansky units/100 ml. of blood plasma = 5-4 to 27 international units of \( \beta \)-glycerophosphate activity per litre.} \]

**Peptic activity.** The reaction of proteases with proteins, involving the breaking of large number of bonds within a single molecule, is not readily expressed as micromoles of substrate transformed. Although an acceptable alternative for reactions such as this would be 'equivalent bonds split', their direct measurement would be difficult. Methods for these enzymes usually depend, therefore, on estimation of the amount of a particular reactive group produced. Whilst this value can be expressed in terms of micromoles of product formed, such units do not have the same strict meaning as those obtained for simpler reactions. An example is the method of Anson and Mirsky for peptic activity.

One Anson and Mirsky unit of peptic activity = 1 mg. tyrosine hydrolysed in 10 min. from the substrate, haemoglobin. The molecular weight of tyrosine is 181, so that 1 Anson and Mirsky (A.-M.) unit

\[ = \frac{1,000}{181} \times \frac{1}{10} \mu\text{moles tyrosine per min.} \]

\[ = 0.055 \mu\text{moles tyrosine per min.} \]

1 A.-M. unit/ml. = 550 \mu\text{moles/min. of peptic activity (against haemoglobin) per litre.} \]

**Amylase.** The Somogyi method for amylase activity measures the amount of reducing sugar formed by the hydrolytic action of the enzyme on starch. The original unit was defined as that amount of enzyme which produces 1 mg. of reducing substances, expressed as glucose, in 30 min. under stated conditions; although this is not
a true representation of the actual course of the reaction, it can lead to an 'international unit', calculated from the number of micromoles of glucose formed, based on the same assumptions as the Somogyi unit.

1 Somogyi unit = 1 mg. glucose produced in 30 min.
   = 1,000  μmoles, where 180 is the molecular weight of glucose
   i.e., 1 Somogyi unit = \( \frac{1,000 \times 1}{180} \times 30 \) μmoles per min.,
   = 0·185 international units
   or approximately 0·2 i.u.

The normal range in Somogyi units for the amylase of blood plasma (up to 200 units/100 ml.) thus becomes

\[ \frac{200}{5} \times 10 = 400 \text{ i.u./litre.} \]

Other methods, involving partial degradation of starch, are usually adjusted to give a normal range similar to that of the Somogyi method; the same conversion factor can thus be applied to them.

**ISOCITRIC DEHYDROGENASE** The method for this enzyme involves the use of N.A.D.P. (T.P.N.)\(^1\), and the unit is defined as that amount which will produce 1 millimicromole of the reduced form of the coenzyme per hour (Wolfson and Williams-Ashman).

Since 1 mμmole = 0·001 μmole

1 Wolfson unit = 0·001 \( \times \frac{1}{60} \) μmole/min.

and since Wolfson units are expressed per ml., they will be equal to

\[ 0·001 \times \frac{1}{60} \times \frac{1,000}{1} \mu\text{moles/min./litre} = 0·0167 \mu\text{moles/min./litre} \]

The normal range of isocitric dehydrogenase is given by Wolfson and Williams-Ashman as 55 to 225 units, therefore the normal range in μmoles/min./litre is 0·9 to 3·7.

**ENZYMES DETERMINED WITH N.A.D. (D.P.N.)**\(^3\) Malic dehydrogenase (Wacker et al.), transaminases (Karmen), and lactic dehydrogenase (Wroblewski and LaDue).

One conventional unit = amount of enzyme which will produce a decrease in optical density (O.D.) at 340 μm of 0·001/min. under the conditions described for the method. (Change in O.D. accompanies oxidation of the coenzyme.)

Since 1 μmole reduced N.A.D./ml. has O.D. of 6·5/cm. at 340 μm., 1 μmole in the 3 ml. reaction mixture will have O.D. of 2·1.

1 conventional unit = \( \frac{0·001}{2·1} \) μmole/min.

= 0·00048 μmole/min. say, 0·0005 μmole/min.

\( \therefore \) 1 conventional enzyme unit/ml. = 0·0005 μmoles/min./ml. or 0·5 μmoles/min./litre.

The commonly accepted normal range of 25 to 100 malic dehydrogenase units/ml. corresponds to 12·5 to 50 μmoles/min./litre. The normal range for glutamic oxaloacetic transaminase of 9 to 32 units/ml. corresponds to 4·5-16 μmoles/min./litre. For glutamic pyruvic transaminase 5-30 units/ml. corresponds to 2·5-15 μmoles/min./litre. The normal range for lactic dehydrogenase of 100 to 600 units/ml. corresponds to 50-300 μmoles/min./litre.

These examples illustrate how the results of enzyme investigations by existing methods can be rephrased in terms of micromoles per minute. A list of conversion factors of many of the enzymes at present employed for diagnostic purposes is given in the table.

**FACTORS FOR CONVERSION OF CONVENTIONAL UNITS TO INTERNATIONAL UNITS PER LITRE FOR ENZYMES OF CURRENT DIAGNOSTIC SIGNIFICANCE**

The above conversion factors have been rounded-off to facilitate conversion while retaining the degree of significance of the original results.

1 Nicotinamide—adenine dinucleotide phosphate (triphosphopyridine nucleotide).
2 Nicotinamide—adenine dinucleotide (diphosphopyridine nucleotide).
The above conversion factors have been rounded-off to facilitate conversion while retaining the degree of significance of the original results.

NOMENCLATURE OF ISOENZYMES

The discovery that a particular type of enzyme activity may apparently be associated with more than one protein and the diagnostic implications of this finding have resulted in an increasing number of references to these multiple molecular forms of enzymes (variously described as isoenzymes or isozyms) in the literature of chemical pathology. The lactate dehydrogenase (L.D.H.) activity of human tissues, for example, is made up of various proportions of five L.D.H. isoenzymes which are distinguishable by electrophoretic or other means.

In the absence of any officially agreed system of nomenclature, some degree of confusion has arisen in the numbering of these L.D.H. fractions; some workers designate the most rapidly anode-migrating isoenzyme L.D.1, and the electrophoretically slowest L.D.6, while the reverse convention is followed in other publications. The Standing Committee on Enzymes of the International Union of Biochemistry is now attempting to formulate a standard nomenclature which, it is hoped, will shortly be published. Until its report is available, authors should state clearly which convention of isoenzyme numbering they are following.

The suggestions set out above for expressing enzymes in international units and on nomenclature for isoenzymes are recommended and approved by the Technical Methods Committee and the Committee on Chemical Pathology of the Association of Clinical Pathologists.

The late E. J. KING
D. W. MOSS

CORRECTION

In the Discussion in the paper 'Urea distribution in renal failure' by Blackmore et al. (J. clin. Path., 1963, 16, 235) the formula on efficiency index in the footnote should read:

Efficiency index = \[ \frac{U_c - U_s}{U_e} \]
