**The Cytology and Cytochemistry of Acute Leukaemias**

Dr. Hayhoe’s studies on the cytochemistry of leukaemic cells are well known. This book represents the result of such studies and includes data pertaining to haemopoietic tissue, with emphasis on acute leukaemia investigated in the M.R.C. leukaemia trial. The object of the study was to find accurate criteria to differentiate the various types of primitive cells. Blood and marrow films were stained by Romanowski and four cytochemical methods. A large number of morphological and staining characteristics were recorded, and the results analysed by computer. Four groups appeared which are shown to correspond to the conventional type of acute leukaemia, and these are further compared with the biological characteristics of the cases. A most interesting chapter considers the significance of the cytochemical findings and speculates on the nature of the leukaemic change. Evidence is brought forward to support the view that there are two types of haemopoietic stem cell, accounting for the clear separation of lymphoblastic leukaemias from the other types. Full details are given of the various staining techniques employed, and there is a useful summary of the features most helpful in differentiating the various types of acute leukaemia. A large number of excellent photomicrographs are included.

This small book contains a wealth of stimulating ideas, and must be considered essential reading for all interested in leukaemia.

**D. Robertson Smith**

**Metabolic Disorders of Domestic Animals**

This book is a short review of some of the biochemical changes that occur in metabolic disease of domestic animals. Though the subject is of most concern to veterinary surgeons and pathologists it makes fascinating reading for the clinical pathologist. The discussion of salt and water metabolism and disorders of calcium, magnesium, and phosphate metabolism are of particular interest. The section concerned with bovine ketosis will attract the attention of those interested in diabetic ketosis. There are a number of tables with comparative inter-species data such as blood and plasma volume, plasma proteins, and plasma glucose.

**M. G. Rinsler**

**Allergy and Tissue Metabolism**

Much of the most useful information in modern research comes from workers engaged in what are sometimes called ‘fringe subjects’. Therefore, it happens that publications in journals of disciplines other than his own make it difficult for the general worker to keep abreast of the latest advances. This applies particularly to a complex subject such as allergy, where substantial contributions have come from such basic medical sciences as physiology, pharmacology, biochemistry, bacteriology, and experimental pathology. Dr. Smith and his publishers deserve much congratulation for attempting to synthesize these various aspects of research.

The book commences with a general account of the immunological basis of allergy and a detailed consideration of anaphylactic shock. A discussion of the part played by the cellular elements, such as mast cells and eosinophils, is followed by the prospectus and functional significance of histamine, bradykinin, serotonin, and the ‘slow-reaching’ substances in anaphylaxis. The concluding chapters deal with anaphylaxis, intermediary metabolism, and therapeutic control of allergic disease. The account of this large field is very readable and very concise, comprising only 94 pages of text. This fact, together with a very adequate list of references, makes it most suitable to recommend to general pathologists as well as to students of research.

**Electronic and Computer-Assisted Studies of Bio-medical Problems**

This book is a transcript of a three-day meeting sponsored by the National Institute of Health and the U.S. Public Health Service to look into the prospects for developing electronic computers and related equipment to aid the life sciences. Regrettably the date of the meeting is not stated but presumably it was held in the latter half of 1963. Thirty-four experts drawn from industry, applied electronics, basic science, and medicine took part in the proceedings but no formal papers were read. The text consists largely of spontaneous and often spirited and revealing discussion, skilfully guided by Otto Schmitt, Professor of Biophysics in the University of Minnesota. Topics discussed include the data which should be recorded and electronically extracted for computer input, the electronic and computer techniques which should be utilized, the characteristics of magnetic tape recorders which are of importance, and the features which are desirable in an electronic computer designed specially to serve the needs of research in the life sciences.

Within the space of a decade computers have made a remarkable impact on certain branches of science and industry and are about to break into everyday medicine. This book, however, will not provide suitable reading for
