benefit to the individual patient but also of economics.

Although the book can be highly recommended to all concerned in the treatment of congenital coagulation disorders, and provides an excellent account of their diagnosis and everyday management, including details of laboratory techniques, it should be read as an argument for referring major surgical or accident cases to the authors' own unit, rather than as an instruction manual to enable others to cope with such problems. The acquired coagulation disorders are outside the scope of the book, and it is perhaps a pity that this is not made plain in its title.

INTERNATIONAL REVIEW OF EXPERIMENTAL PATHOLOGY
VOL. 4 Edited by G. W. Richter and M. A. Epstein.

When the first volume of this series appeared it was widely hailed as a major and long-awaited contribution to biological reviews. The highly favourable impression created by Volume I was to some extent lessened by some aspects of the intervening annuals. This was due not to any lowering of the standards of originality or scholarship but rather to a tendency to the esoteric, i.e., to dealing with specialized areas of specialist topics. The latest volume, however, returns triumphantly to the concept of the first in that all five contributors deal with topics of current and general importance to pathology.

The first article by D. F. Parsons deals with the structure and function of mitochondria and admirably illustrates the role of the electron microscope in effecting this correlation to the point where the two concepts merge into one another.

The second contribution, by D. G. ScarpeI and N. M. Kanczak, is essentially methodological and deals with ultrastructural cytochemistry. In the course of the chapter, many applications of the methods are presented and critically discussed.

The third article, by A. E. M. McLean, Elizabeth McLean, and J. D. Judah, is devoted to hepatic necrosis induced and modified by drugs. This is a masterly and highly critical review of a field of fundamental importance to pathology since it represents the spearhead of the attack on the problems of cell dysfunction and death.

The fourth chapter is an account by A. S. Cohen of the present state of the amyloid problem. It presents not only a comprehensive review but also a succinct account of the author's own research which has revolutionized all ideas about this substance. Indeed the volume is worth purchasing for this chapter alone.

Finally comes another subject, equally important and equally complex, that of complement, especially its haemolytic function and chemical properties. This article, by P. G. Klein and H. J. Wellensiek, is well up to the standard of the other four chapters and is a remarkably lucid exposition.

The volume as a whole represents an invaluable compendium of information on subjects of vital importance presented and discussed with clarity and judgment. It is well worth the purchase price to any pathologist who wishes to keep abreast of advances in his subject.

W. G. SPECTOR

The second edition is an improvement on the previous volume and a number of controversial points have been omitted. This is quite a large work and the subject is dealt with from the morbid anatomist's point of view. The chapter headings, which have a regional basis, are similar to those in the previous edition, but a chapter has been added on chromosomal anomalies. The chapter concerned with the newborn infant has been largely rewritten and important changes are seen in connexion with cardiovascular disorders and diseases of the liver and kidneys. There are separated accounts of diseases resulting from viruses, protozoa and fungi, and from worm infestation. Some of these are of course more useful to those working in tropical countries or in North America, but their inclusion adds to the value of the book as a reference work.

The volume is well produced and copiously illustrated. The photomicrographs are of a high order with only few exceptions. The bibliography is extensive and is grouped under subject headings at the end of each chapter. Some of the references are not particularly recent but they are representative of both the American and European literature.

This book will be of great value to all those who have an interest in paediatric pathology. The highly personalized style of the author, and the way in which some of his views are expressed, may not commend him to other paediatric pathologists, but as a reference work this book is not likely to be superseded for some time to come.

A. E. CLAIREAUX

HYALURONIDASE AND CANCER By E. Cameron. (Pp. xiii + 245; illustrated. 50s.) Oxford: Pergamon Press. Dr. Cameron's thesis is simple: 'It becomes possible to relate all the principal morphological, biochemical, experimental, and therapeutic features of cancer to the single common denominator provided by the hyaluronidase-substrate reaction. The continuous release of hyaluronidase is the fundamental difference between the neoplastic and the normal cell.'

It is a breathtaking recipe and so far from the general view of cancer that the question at once arises, who is out of step? A few points suffice. Differentiation, for example, and its variation from tumour to tumour, the phenomena of anaplasia and metaplasia are passed by entirely. Progression is ignored and hormone-dependence is dealt with thus: 'Is it not possible that regressions occur in patients who have "hormone-sensitive" ground substance rather than in tumours which have "hormone-dependent" cells?' To which one answer is, why, then, do not tumours of all organs respond in similar proportions to endocrine therapy?

Naturally the lack of contact inhibition between tumour cells in culture, where there is no ground substance for hyaluronidase to act upon, is not mentioned. Indeed the whole concept of neoplastic disease built up by experiment and clinical observation is either ignored or distorted to fit somehow into Dr. Cameron's fantastic hypothesis. The tragedy is that probably there is much
