The concentration of prorenin quantified in the ovarian cysts was, however, comparable with the range of values reported for normal plasma (10–40 ng A1 ml⁻¹ h⁻¹). These data show the presence of prorenin in some ovarian cysts. The concentration of prorenin, however, was not sufficiently high to consider fluid from these cysts as a useful source of the zymogen for further study. Future work is important to define the role of the ovarian renin-angiotensin system in human reproduction.

A particular feature of the series is the inclusion of a Notes section at the end of chapters, where one finds expert tips that can enable one to apply these techniques even as a novice. Although there are some omissions, such as the freezing of cells other than hybridomas. I would recommend this book to all those considering using tissue culture in their work.

PA HALL

This book contains four large chapters dealing with induction of suppressor cells by immunostimulants, control of natural killer cells by suppressor cells, suppressor cells in human malignancies, and finally suppression of suppressor cells and malignancy in experimental animal models. It is a very curious book. The authors go into great detail in the description of experiments designed to elucidate aspects of suppression. All of the conflicting data from different studies and different models, however, served to confuse this reviewer rather than enlighten him. Some attempt is made to summarise the results with large tables at the end of certain chapters, but these are lists and are not particularly useful. The central question stated at the beginning of the book, of whether suppressor cells permit malignancy or are a result of it, remains unanswered, and substitution of suppressor cells is rather contentious these days, it really is rather hard to make sense of the central theme of the book. There is a lot of discussion of suppressor macrophages but no mention anywhere of tumor necrosis factor z. The book would have been topical in the early 80s but now it seems rather anachronistic, dealing as it does with cellular rather than molecular immunology. Virtually all of the experiments described in this book seem to be rather old, as is the literature cited. Towards the end of the book is a section on the T cell receptor with references up to 1987, but this appears to have been added on at the end in an attempt to make the book more topical. It is very poorly illustrated, containing only three figures, the first of which appears on page 50. Clearly a great deal of work has gone into the book and it contains 860 references, but more attention to presentation and less to documentation would have helped. It is unlikely to be of use to the general pathologist, clinician, or immunologist but might be of interest to afficionados of tumour immunology.

TT MACDONALD

This book consists of a series of review chapters written by specialists from several European countries and centres in the USA on different topics relating to surgical pathology. The text is generally easy to read and well illustrated. Most articles are above average interest and this was shown clearly by the book being temporarily appropriated by my wife (who is also a histopathologist) so that she could read several chapters.

I found the best chapters were those on cutaneous histiocytoses in children, Hodgkin's disease, chromogranin A and B in neuroendocrine tissues, thymic tumours, campylobacter in gastrointestional disease, mucosal prolapse syndrome, and the surgical pathology of the anal canal, but that probably reflects my range of interests. Other topics covered were extrinsic allergic alveolitis, pulmonary vascular neoplasms (I hadn't realised there were so many possibilities), telangectatic osteosarcoma of bone, sarcomatoid carcinomas of the breast and microcapillary hyperplasia of the breast. Chapter 1 discussed the importance of right and left handedness in pathologists and its association with happiness and other factors. The author admits it is a relatively unscientific enquiry but nevertheless it is thought provoking.

Overall, a worthwhile book which I would recommend to practising surgical pathologists who borrow my copy. I should say, however, that it falls a little short of the consistently high standards achieved by Recent Advances in Histopathology edited by DR TURNER.

This is a highly illustrated book written by three American authors who perform their own fine needle aspirations; it could have been subtitled “A manual of head and neck cytopathology”. It is divided into five chapters. The first provides a practical guide to the technique of performing a fine needle aspiration (FNA), as well as preparing smears and staining them. There are useful guidelines on the general interpretation of FNA material and the reporting of results. Three separate chapters follow on lymph node, thyroid, and salivary gland cytopathology. A final general chapter discusses branchial cleft cysts, lymphangioma, carotid body tumour, and neuroblastoma.

Apart from the use of a North American classification scheme for the non-Hodgkin's lymphomas, I cannot fault this book. Each chapter contains a body of text in which the organ system concerned is discussed. Problems of interpretation and differential diagnosis as they pertain to FNA material are presented clearly and succinctly, including some useful tables. The text is followed by illustrated case reports which show in both colouro and in black and white, the cytological, histological, clinical, and occasionally, radiological appearances of the pathology under discussion. Some electron micrographs are also provided.

The book is generally well balanced, the illustrations are of adequate quality, and several up to date reference lists are provided. I think it should appeal to a general audience, and I would recommend it to pathologists,
