CORRESPONDENCE

If you have a burning desire to respond to a paper published in Journal of Clinical Pathology, why not make use of our “rapid response” option? Log on to our website (www.jclinpath.com), find the paper that interests you, and send your response via email by clicking on the “eLetters” option in the box at the top right hand corner.

Providing it isn’t libellous or obscene, it will be posted within seven days. You can retrieve it by clicking on “read eLetters” on our homepage.

The editors will decide as before whether to also publish it in a future paper issue.

An early lesion of pulmonary carcinosarcoma: possible diagnostic problem in frozen section interpretation

Sarcomatoid carcinoma is a rare malignant diagnostic problem in frozen tissue interpretation. The case history of a 69-year-old man who had smoked 20 cigarettes a day for 48 years is reported. Computed tomography showed an irregular shadow of 19 mm maximum diameter in the S3 region of the right lung. Because thoracoscopic biopsy with frozen sections was performed, a diagnosis of small carcinomas could be made. The tumour was 2 cm in size. Immunohistochemically, the carcinomatous cells were positive for antibodies to various cytokteratinins, including AE1/AE3 (prediluted; Dako, Carpinteria, California, USA). They were negative for vimentin (prediluted; Dako). Sarcomatous cells were negative for cytokteratinins and strongly positive for vimentin (prediluted; Nichirei, Tokyo, Japan). It is important to know just how small a carcinosarcoma of the lung can be, because the existence of small carcinosarcomas suggests that the sarcomatoid transition could take place relatively early. In the literature, small carcinosarcomas of the lung are encountered extremely rarely. Koss et al reviewed the literature and found 34 cases that fit the WHO definition of pulmonary carcinosarcoma, among which only two were 2 cm in size. Early lesions of carcinosarcoma of the lung may necessitate intraoperative diagnosis. Care should be taken in the interpretation of a frozen section because insufficient sampling could lead to an erroneous diagnosis, such as reactive fibroblastic proliferation.

Caution should be taken in using CD31 for distinguishing the vasculature of lymph nodes

When interpreting lymph node biopsies it is sometimes necessary to distinguish the different compartments of the lymph node. In normal lymph nodes the task may be easily accomplished, but it can be difficult for effaced lymph nodes. We compared the usefulness of routinely used endothelial markers for distinguishing sinuses from vascular channels in the lymph node.

Eighteen lymph nodes—seven normal lymph nodes from a patient with colon cancer (patient 1), eight from a patient affected by diffuse large B cell lymphoma of the stomach (patient 2), and three from a patient with anaplastic large cell lymphoma (ALCL) (patient 3)—were selected from the archives of the department of pathology, Kariya General Hospital, Japan. The tissues were fixed in 10% formalin and embedded in paraffin wax. Standard tissue sections, 6 µm thick, were stained with haematoxylin and eosin. Immunohistochemical staining was performed by means of the Ventana (Ventana, Tucson, Arizona, USA).

The primary antibodies used were commercially available antibodies directed against factor VIII (prediluted; Dako, Carpinteria, California, USA), CD31 (prediluted; Dako), and CD34 (prediluted; Dako). Positive and negative controls were used in each assay. For anti-factor VIII, desmased sections were pretreated in a microwave for 15 minutes, in 95°C 10mM citrate buffer at pH 6.0. For anti-CD31, sections were pretreated in two ways, either with trypsin or by the microwave method.

Anti-CD34 was applied to the sections of all lymph nodes from patients 1 and 2, but only decorated vascular channels. For anti-factor VIII, background staining was very intense in the sinuses. Anti-CD34, when pretreated with either trypsin in the microwave, was positive not only for the endothelium of vascular channels but also for the lining cells of sinuses. When applied to the lymph nodes from patient 3, all the tumour cells were confined within spaces that were lined by CD31 positive cells (fig 1). The application of anti-CD34 suggested that these spaces were in fact sinuses (fig 2), leading to the conclusion that this case represented ALCL with a sinus pattern of involvement.

The sinuses of the lymph node are different from vascular channels in that they are not lined with endothelium. CD31 is believed to be a highly specific marker for endothelial cells. Recently, however, McKenney and associates showed that the expression of CD31 by macrophages could easily be detected on formalin fixed, paraffin wax embedded sections, causing misdiagnosis in surgical pathology practice. This characteristic of CD31 may also be important in distinguishing the compartments of the lymph node or spleen. The presence of CD31 cannot be used to distinguish sinuses from capsular or trabecular sinuses because specific dendritic cells that line the sinuses of lymph nodes are also positive for CD31. "" Apparent positivity for CD31 could lead to the misinterpretation of sinuses as vascular channels. CD31 is expressed by a variety of cells, and can be detected not only in endothelial cells, but also in reactive fibroblasts and some types of benign and malignant mesenchymal neoplasms. Applying...
Cirrhosis with steatohepatitis following longterm stilboestrol treatment

Diethylstilboestrol, which is chemically related to the female hormone oestrogen, was the main form of androgen suppression in the treatment of advanced prostate cancer up until the late 1980s. Although luteinising hormone releasing hormone (LHRH) analogues have superseded diethylstilboestrol in six post-mortem cases with a history of diethylstilboestrol treatment for prostate cancer. In addition, two documented cases of hepatocellular carcinoma have been reported following longterm stilboestrol treatment.

Interestingly, non-alcoholic steatohepatitis is seen not only with oestrogenic drugs such as stilboestrol, but also with the partial agonist drug tamoxifen. It is known that steatohepatitis inducing drugs such as stilboestrol accumulate within mitochondria, resulting in ATP depletion and lipid peroxidation of hepatocytes.

Diethylstilboestrol was once the main alternative to orchietomy in the treatment of prostate cancer. However, its potential side effects, which include breast enlargement and cardiotoxicity, mean that it has been largely superseded by LHRH analogues with superior safety profiles. Although the use of stilboestrol has declined, its reintroduction to large scale clinical use has recently been proposed, particularly for early hormone refractory disease. This case report emphasises the need for regular monitoring of liver function tests in those receiving such treatment. It also serves as a further example of a steatohepatitis inducing drug.

BOOK REVIEWS

Cytopathology of the Breast

McKee GT. (£130.00.) Oxford University Press, 2002. ISBN 0 19 514006 0.

Grace McKee’s recent publication provides an extremely comprehensive overview of breast entities. Although it is entitled “Cytopathology” it encompasses much more, providing clinical and histopathological details, in addition to cytological features of a very wide range of breast entities.

The initial chapters provide detailed discussions of normal breast histology and cytology; methods of aspiration, smear preparation, and laboratory techniques, including sections on the reporting of cytological specimens and the limitations of cytology. Although concentrating on fine needle aspiration biopsy material, exfoliative cytology of nipple secretions and ductal lavage specimens are also included. Subsequent chapters are organised such that entities are introduced with clinicopathological descriptions followed by gross, histological, then cytological features. For many entities this is followed by a summary of cytological findings. There are numerous photomicrographs of both histological and cytological features, which are of excellent quality, the discussions are detailed, and references are extensive. The very comprehensive nature of the text is perhaps a slight weakness, for even the numerous photomicrographs cannot fully illustrate the features of some of the lesions discussed, and although the limitations of cytological diagnoses are described, it is not always clear whether the diagnosis of some entities from the cytological specimen is practically feasible.

The book is splendidly written and beautifully illustrated. In the context of the recent changes in breast diagnosis and the increased complexity of breast lesions, an in depth review of breast from the cytological and histological perspectives is timely. This book will be a useful reference text for those involved in diagnosing breast lesions by either cytology or histology, and may also be recommended to clinicians who take their own cytological breast specimens.

The Diagnosis of Lymphoproliferative Diseases: An atlas

The authors set out clearly in their preface how and why this atlas came into being. An atlas in pathology is usually a compendium or analecta of illustrations attended by short annotations. As a rule, atlases don’t make the “go for” book list when it comes to a diagnostic crunch. This book is more than an atlas. Condensed into a mere 262 (258 if one really wants to be pedantic) pages, crammed with excellent colour illustrations, this book is also full of facts, suggestions and guidelines. From the introduction (where one of the authors indulges himself with a military reference!) which contains very useful tables of antibodies used in haematopathology through to the index at the back, I found the book extremely user friendly and written in an almost conversational style. This book has everything a general surgical pathologist is ever likely to encounter by way of lymphoproliferative diseases. I daresay the card carrying haematologist will be hard pressed to find an entity that is not covered. The book addresses all the diagnostic dilemmas that cause non-afficionados of matters lymphoproliferative to become weak kneed about in a concise, coherent, and informative manner. There is no doubt that this is an essential benchmark for any department of pathology. With all the colourful pictures, the price is competitive and not exorbitant. Professors Gatter and Delsol are to be congratulated on their pithy, epigrammatic offering, which really does prove that size doesn’t really matter.

R Chetty

CALENDAR OF EVENTS

Full details of events to be included should be sent to Maggie Butler, Technical Editor JCP, The Cedars, 36 Queen Street, Castle Hedingham, Essex CO9 3HA, UK; email: maggie.butler2@btopenworld.com

A CP Management Course for Pathologists, 2003

10–12 September 2003, Hardwick Hall Hotel, Sedgefield, County Durham, UK
Further details: Ms Valerie Wood, ACP Central Office, 189 Dyke Road, Hove, East Sussex, BN3 1TL, UK (Tel: +44 01273 777500; Fax: +44 01273 773303; Email: valerie@pathologists.org.uk)

Dermatopathology Update

10–13 September 2003, Fairmont Copley Plaza Hotel, Boston, Massachusetts, USA
Further details: Tel: +1 617 384 8600; Email: hms-cme@hms.harvard.edu; website: wvw-cme.hms.harvard.edu

Predictive Oncology Meeting

15–16 September 2003, Solent Hotel, Fareham, Portsmouth, UK
Further details: Professor Ian A Cree, Translational Oncology Research Centre, Department of Histopathology, Michael Darmady Laboratory, Queen Alexandra Hospital, Cosham, Portsmouth PO6 3LY, UK. (Tel: +44 (0)23 92 286378; Fax: +44 (0) 23 92 286379; Email: ian.cree@porthosp.nhs.uk)

Medicare India

6–8 April 2004, Pragati Maidan, New Delhi, India
Further details: Rob Grant, Kinex Log, 5 New Quebec Street, London W1H 7DD, UK. (Tel: +44 (0) 207 723 8020; Fax: +44 (0) 207 723 8060; Email: rob.grant@kinexlog.com; Website: www.medicare-expo.com or www.kinexlog.com)
