Gemella bacteraemia characterised by 16S ribosomal RNA gene sequencing

P C Y Woo, S K P Lau, A M Y Fung, S K Chiu, R W H Yung, K Y Yuen

Aims: To define epidemiology, clinical disease, and outcome of gemella bacteraemia by 16S RNA gene sequencing. To examine the usefulness of the Vitek, API, and ATB systems in identifying two gemella species.

Methods: All α haemolytic streptococci other than Streptococcus pneumoniae isolated from blood cultures during a six year period were identified by conventional biochemical methods, the Vitek system, and the API system. 16S rRNA gene sequencing was performed on all isolates identified by both kits as gemella with ≥95% confidence or by either kit as any bacterial species with <95% confidence. The ATB expression system was used to identify the two isolates that were defined as gemella species by 16S rRNA gene sequencing.

Results: Of the 302 α haemolytic streptococci other than S pneumoniae isolated, one was identified as Gemella morbillorum, and another as Gemella haemolysans by 16S RNA gene sequencing. The patient with monomicrobial G morbillorum bacteraemia was a 66 year old man with community acquired infective endocarditis with septic thromboemboli. The patient with G haemolysans bacteraemia was a 41 year old woman with hospital acquired polymicrobial bacteraemia during the neutropenic period of an autologous bone marrow transplant for non-Hodgkin’s lymphoma, the first case of its kind in the English literature. The API and ATB expression systems only identified the second strain as G haemolysans at 94% and 99% confidence, respectively, whereas the Vitek system identified none of the two strains correctly at >70% confidence.

Conclusions: Gemella bacteraemia is uncommon. 16S rRNA gene sequencing is the method of choice for identification of gemella and gemella-like isolates.

Since the discovery of the polymerase chain reaction (PCR) and DNA sequencing, comparisons of the gene sequences of bacterial species have shown that the 16S rRNA gene is highly conserved within a species and among species of the same genus, and hence can be used as the new standard for speciation of bacteria. Using this new standard, phylogenetic trees, based on base differences between species, are constructed, and bacteria are classified and reclassified into new genera. Recently, we have reported the use of this technique for the identification of bacterial strains with ambiguous biochemical profiles, species that are rarely encountered clinically, and a bacterium that is non-cultivable. In addition, we have also reported the discovery of a novel clinical syndrome and three novel species, and the characterisation of β haemolytic Lancefield group G streptococcal bacteraemia and Granulicatella adiacens and Abiotrophia defectiva bacteraemia.

“We have recently shown that a large number of bacterial strains identified as gemella species by commercially available phenotypic systems are actually Granulicatella adiacens”

Members of the genus gemella consist of catalase negative, facultative anaerobic, Gram positive cocci that phenotypically resemble viridans streptococci. Traditionally, the identification of, and hence the study in the epidemiology of and spectrum of clinical diseases caused by gemella species depend on the phenotypic characterisation of suspected isolates. However, we have recently shown that a large number of bacterial strains identified as gemella species by commercially available phenotypic systems are actually Granulicatella adiacens. No data are currently available that have used 16S rRNA gene sequencing as the gold standard. Therefore, in our study, we used 16S rRNA gene sequencing, assisted by traditional phenotypic tests, to describe the epidemiology, clinical diseases, and outcome of gemella bacteraemia. We also examined the usefulness of the Vitek system (bioMerieux Vitek, Hazelwood, Missouri, USA), the API system (bioMerieux Vitek), and the ATB expression system (bioMerieux Vitek), which are commonly used for microbial identification of α haemolytic streptococci in clinical microbiology laboratories, for the identification of the two gemella isolates.

METHODS AND MATERIALS

Patients and microbiological methods

The patients with gemella bacteraemia in our study were hospitalised at the Queen Mary Hospital in Hong Kong during a six year period (July 1995 to June 2001). All clinical data were collected as described in our previous publication. The BACTEC 9240 blood culture system (Becton Dickinson, Sparks, Maryland, USA) was used. To identify potential cases of gemella bacteraemia, in addition to identifying all blood culture isolates by standard conventional biochemical methods, the Vitek system (GPI; bioMerieux Vitek) and the API system (20 STREP; bioMerieux Vitek) were used for species identification of all α haemolytic streptococci other than Streptococcus pneumoniae isolated from blood cultures during the six year period. 16S rRNA gene sequencing was performed on all isolates that were identified by both kits as gemella with ≥95% confidence, or by either kit as any bacterial species with ≥95% confidence. The results were compared with the 16S rRNA gene sequence.

Abbreviations: MIC, minimum inhibitory concentration; PCR, polymerase chain reaction
< 95% confidence. To examine the usefulness of the ATB expression system (ID32 STREP; bioMérieux Vitek) for the identification of gemella species, this system was also used for identification of the two isolates that were finally defined as gemella species by 16S rRNA gene sequencing. Antimicrobial susceptibility was undertaken by the E test for penicillin and the Kirby Bauer disk diffusion method for the other antibiotics using Muller Hinton agar supplemented with 5% horse blood, and the results were interpreted according to the NCCLS criteria for α haemolytic streptococci. Multiple positive blood cultures with the same isolate obtained from the same patient were counted only once.

**Extraction of bacterial DNA for 16S rRNA gene sequencing**

Bacterial DNA extraction was modified from our previously published protocol. Briefly, 80 µl of NaOH (0.05M) was added to 20 µl of bacterial cells suspended in distilled water and the mixture was incubated at 60°C for 45 minutes, followed by the addition of 6 µl of Tris/HCl (pH 7.0), to achieve a final pH of 8.0. The resultant mixture was diluted ×100 and 5 µl of the diluted extract was used for PCR.

**PCR, gel electrophoresis, and 16S rRNA gene sequencing**

PCR amplification and DNA sequencing of the 16S rRNA gene were performed according to our previous publications. Briefly, DNase I treated distilled water and the PCR master mix (which contains dNTPs, PCR buffer, and Taq polymerase) were used in all PCR reactions by adding 1 U of DNase I (Pharmacia, Uppsala, Sweden) to 40 µl of distilled water or PCR master mix, incubating the mixture at 25°C for 15 minutes, and subsequently at 95°C for 10 minutes to inactivate the DNase I. The bacterial DNA extracts and control water (Pharmacia, Uppsala, Sweden) were amplified with 0.5 U Taq polymerase (Perkin-Elmer Cetus, Gouda, The Netherlands). DNase I treated distilled water was used as the negative control. A 10 µl sample of each amplified product was electrophoresed in a 1.0% (wt/vol) agarose gel, with a molecular size marker (Lambda DNA AvaII digest; Boehringer Mannheim) in parallel. Electrophoresis in Tris/borate/EDTA buffer was performed at 100 V for 1.5 hours. The gel was stained with ethidium bromide (0.3 µg/ml) for 15 minutes, rinsed, and photographed under ultraviolet light illumination.

The PCR products were gel purified using the QIAquick PCR purification kit (QIAGen, Hilden, Germany). Both strands of the PCR products were sequenced twice with an ABI 377 automated sequencer according to manufacturer’s instructions (Perkin-Elmer, Foster City, California, USA), using the primers LPW200, LPW201, LPW205, LPW273 (5'-TTAGGGGCTAAAGCGA-3'), and LPW275 (5'-TTGGGGGACTTACCAAAC-3'). The sequences of the PCR products were compared with known 16S rRNA gene sequences in the GenBank by multiple sequence alignment using the CLUSTAL W program, and phylogenetic tree construction was performed using the PileUp method with GrowTrec (Genetics Computer Group Inc, San Diego, USA).

**RESULTS**

16S rRNA gene sequencing

Among a total of 302 α haemolytic streptococci other than *S pneumoniae* isolated from blood cultures of patients admitted to Queen Mary Hospital during the six year period (July 1995 to June 2001), none was identified by both the Vitek system (GPI) and the API system (20 STREP) as any gemella species with > 95% confidence. A total of 74 were identified by either kit as any species with < 95% confidence. PCR of the 16S rRNA genes of these isolates showed bands at approximately 1410 bp. Sequencing of the 16S rRNA genes revealed that one isolate (table 1; patient 1) had > 99% nucleotide identity with the 16S rRNA genes of *G morbillorum* (GenBank accession number L14327), and another (table 1; patient 2) had > 99% nucleotide identity with the 16S rRNA genes of *G haemolysans* (GenBank accession number L14326) (fig 1). Therefore, gemella accounted for 0.7% of bacteraemia caused by α haemolytic streptococci other than *S pneumoniae*.

*Note:* Characteristics of patients with gemella bacteraemia.
is not uncommon to encounter clinical isolates of these rare bacterial species with ambiguous biochemical profiles. Furthermore, even if they are “successfully” identified by the commercial kits, the low prevalence rate would imply a low positive predictive value. In our study, we described our experience in using 16S rRNA gene sequencing to characterise two strains of a rarely encountered bacterial genus, gemella, recovered from blood cultures of our patients in the past six years.

The genus gemella consists of six species. Before 1998, there were only two known gemella species, *G. haemolysans* and *G. morbillorum*. *Gemella haemolysans* was originally classified as *Neisseria haemolysans*, and was subsequently reclassified as *G. haemolysans* in 1960; whereas *G. morbillorum* was originally classified as *Diplococcus morbillorum*, subsequently as *Pneumococcaceae morbillorum*, and was finally reclassified as *G. morbillorum* in 1988. In the past five years, four additional gemella species have been discovered. *Gemella bergeriae* and *G. sanguinis* were recovered from human clinical specimens, whereas *G. palatinum* was recovered from the oral cavity of a dog, and *G. cunicula* from an abscess of a rabbit.

The identification of “gemella-like” species by the commercial kits was unsatisfactory, especially when the Vitek system (GPI) was used. In the present series, the Vitek system (GPI) was not able to identify a single isolate successfully; whereas the API system (20 STREP) identified the both *G. morbillorum* and *G. haemolysans* strains as 60% *Leuconostoc* sp., 28% *Streptococcus mitis*, and 94% *G. haemolysans*, 6% *G. morbillorum*, respectively. The ATB expression system (ID32 STREP) identified the *G. morbillorum* and *G. haemolysans* strains as “unidentified” and 99% *G. haemolysans*, respectively.

**Patient characteristics**

Table 1 summarises the characteristics of the two patients with gemella bacteraemia. Briefly, the first patient, a 66 year old man, was admitted because of occasional abdominal and low back pain for one month. He was afebrile. Examination revealed a collapsing pulse, an early diastolic murmur of grade 3/6 at the left lower sternal border, and a pulsatile mass in the abdomen. Computer tomography of the abdomen confirmed an infrarenal abdominal aortic aneurysm of 7.5 cm in diameter, without signs of rupture. Transthoracic echocardiogram showed severe aortic regurgitation and vegetations on both the aortic and mitral valves. Three sets of blood cultures all recovered the same strain of *G. morbillorum*. He was treated for community acquired infective endocarditis with intravenous penicillin G and netilmicin. He developed sudden retrograde amnesia 17 days after admission. Magnetic resonance imaging of the brain showed multiple subacute infarcts at both occipito–temporal regions, compatible with septic thromboembolism. Intravenous antibiotics were continued for a total of six weeks with residual memory loss. He subsequently underwent an elective endoanuerysmectomy with insertion of an aortic graft and was discharged two months from admission.

The second patient, a 41 year old woman with non-Hodgkin’s lymphoma, was admitted because of autologous bone marrow transplantation. On day two postmarrow infusion, she developed neutropenic fever. Examination did not reveal a heart murmur or other focus of infection. Blood cultures were performed and recovered *G. haemolysans*, *S. mitis*, and *Escherichia coli*. She responded to empirical intravenous imipenem and subsequent blood cultures were negative. Her bone marrow engrafted on day 15.

**DISCUSSION**

The identification of infrequently encountered bacterial species in clinical microbiology laboratories has always been a problem. Because the number of reference strains used for building up databases in commercial kits is usually small for rare bacteria, it

**Phenotypic characterisation and identification of gemella by commercial systems**

Gram smears of the two isolates showed Gram positive cocci in pairs. The Vitek System (GPI) identified the *G. morbillorum* and *G. haemolysans* strains as 63% *G. morbillorum*/*S. agalactiae/ *S. acidominimus*, 22% *S. pneumoniae*, and 68% *G. morbillorum*/*S. agalactiae/ *S. acidominimus*, 24% *S. pneumoniae*, respectively. The API system (20 STREP) identified the *G. morbillorum* and *G. haemolysans* strains as 60% *Leuconostoc* sp., 28% *Streptococcus mitis*, and 94% *G. haemolysans*, 6% *G. morbillorum*, respectively. The ATB expression system (ID32 STREP) identified the *G. morbillorum* and *G. haemolysans* strains as “unidentified” and 99% *G. haemolysans*, respectively.
species isolated from clinical specimens were highly sensitive to penicillin G and ampicillin. In 1993, a strain of glycopeptidase resistant *G. haemolytica* that showed reduced susceptibility to penicillin (minimum inhibitory concentration (MIC) of 0.5 µg/ml) was recovered from the blood culture of a 20 month old boy. In 1996, another strain of *G. morbillorum* that was resistant to penicillin (MIC of >4 µg/ml) was recovered from the blood culture of an 11 year old girl with nasopharyngeal Burkitt's lymphoma. In our present series, one of the two gemella strains showed reduced susceptibility to penicillin (MIC of 0.5 µg/ml). Furthermore, it was also resistant to erythromycin, clarithromycin, and azithromycin. Because amoxicillin or macrolides are used as prophylaxis for infective endocarditis, the rising incidence of penicillin and macrolide resistance may mean the failure of these agents in the prophylaxis of infective endocarditis, and one of the two patients reported here had gemella endocarditis. The other patient was a bone marrow transplant recipient who had gemella bacteremia during the pre-engraftment period and the oral flora was the source of the bacteremia in this case.

**Take home messages**

- Gemella bacteremia is rare and 16S rRNA gene sequencing should be the method of choice for identification of gemella and gemella-like isolates.
- The identification of *gemella*-like species by the commercial kits was unsatisfactory, especially when the Vitex system (GPI) was used.
- Species of gemella are important causes of infective endocarditis and one of the two patients reported here had gemella endocarditis.
- The other patient was a bone marrow transplant recipient who had gemella bacteremia during the pre-engraftment period and the oral flora was the source of the bacteremia in this case.
