Gastrin (G) cells and somatostatin (D) cells in patients with dyspeptic symptoms: *Helicobacter pylori* associated and non-associated gastritis

Y Liu, G D C Vosmaer, G N J Tytgat, S-d Xiao, F J W Ten Kate

**Background:** Gastrin G cells and somatostatin D cells are important regulators of gastric acid secretion and alterations in their relative numbers may play a key role in gastroduodenal disease.

**Aim:** To investigate the effect of *Helicobacter pylori* infection on the density of immunoreactive G and D cells in gastric antral and corpus biopsies from patients with dyspeptic complaints.

**Methods:** One hundred and twenty two patients with dyspeptic complaints had two antrum and two corpus biopsies taken during upper endoscopy. The severity of inflammation and the density of *H pylori* were evaluated semiquantitatively. In addition, the density and distribution of neuroendocrine cells, especially G and D cells, were examined using immunohistochemistry. Patients were divided into three groups, those with *H pylori* positive gastritis, *H pylori* negative gastritis, and histologically normal gastric mucosa.

**Results:** The number of immunoreactive G cells was significantly higher and the number of immunoreactive D cells lower in patients with *H pylori* positive gastritis compared with *H pylori* negative gastritis or histologically normal gastric mucosa. The percentage of G cells as a percentage of mucosal endocrine cells was also raised and that of D cells was decreased.

**Conclusions:** *Helicobacter pylori* infection produces alterations in the number of endocrine cells responsible for regulating acid secretion in relation to intragastric pH and feeding. The alterations correlate best with the severity of inflammation and not with *H pylori* density.

**MATERIAL AND METHODS**

**Trial design**

One hundred and seventy three patients (female to male ratio, 1.25) between the ages of 17 and 78 years (mean, 42; SD, 15.6) undergoing endoscopy for evaluation of dyspepsia were recruited from Dutch family doctors in 1993. Patients who had reflux oesophagitis, peptic ulcers, and malignancy were excluded from our study. Ethics committee approval and informed consent were obtained from each patient. We compared the presence and severity of gastritis with the presence and density of immunoreactive endocrine cells in the gastric mucosa.

**Endoscopy**

All the patients underwent upper gastrointestinal endoscopy. Two antral and two corpus biopsies were obtained. The biopsies were used for histological evaluation and for immunohistological staining for gastrin, somatostatin, and chromogranin. An additional biopsy was obtained for the rapid urease test (CLOtest).

**Abbreviations:** ABC, avidin–biotin complex; D, somatostatin; G, gastrin

**Histological examination**

Specimens were fixed in 10% formalin and routinely processed. Paraffin wax embedded sections were cut into 3–4 μm thick serial sections and stained with haematoxylin and eosin. Giemsa staining was routinely performed to detect the presence or absence of *H. pylori*. The sections were interpreted by two experienced pathologists (TK and YL), who were unaware of the clinical and endoscopic findings.

The following four parameters were evaluated and graded, as suggested by the Sydney system: (1) chronic inflammation, which is scored on the basis of the chronic inflammatory infiltrate in the lamina propria; (2) active component of inflammation through assessing the polymorphonuclear leucocytes (neutrophilic infiltration); (3) atrophy, which is scored on the basis of the proportional loss of the specialised gastric glands, with or without replacement of intestinal metaplastic tissue; areas with lymphoid follicles, dense infiltration, or both were not graded for atrophy; and (4) intestinal metaplasia, which was scored as absent or occupying less than one third, more than one third, or more than two thirds of the mucosa present. For both antrum and corpus, biopsies were assessed semiquantitatively by a score as positive for *H. pylori* if one of the two tests (CLO and

Giemsa staining) was positive and as negative if both tests were negative.

**Immunohistochemistry**

Mucosal biopsies were immunostained with polyclonal antibodies to gastrin, somatostatin, and chromogranin by the avidin–biotin complex (ABC) method (DakoCorp, Copenhagen, Denmark). In brief, sections were dewaxed and rehydrated in graded alcohols. Endogenous peroxidase activity was quenched, antigen retrieval was performed by heating for 10 minutes at 100°C in 0.01M sodium citrate, and non-specific staining was reduced by a blocking step. The rabbit antibodies against gastrin (1/1000 dilution), somatostatin (1/1600 dilution), and chromogranin (1/1000 dilution) were applied in phosphate buffered saline containing 1% bovine serum albumin and 0.1% Triton and incubated overnight at 4°C (all three antibodies were from DakoCorp). The following day, a three step detection method was used as described previously, using a biotinylated goat anti-rabbit immunoglobulin antibody (Dako; 1/500 dilution). Detection was performed with horseradish peroxidase conjugated ABC (Dako) for 60 minutes and peroxidase activity was detected with diaminobenzidine (fast DAB; Sigma, St Louis, Missouri, USA), according to the manufacturer's instructions, resulting in the formation of a brown reaction product. Finally, the sections were briefly counterstained with haematoxylin, dehydrated in graded alcohols, and mounted. Further controls consisted of omitting the primary and secondary antibodies and the use of an appropriate immunoglobulin control.

Only sections showing the entire axis from the superficial luminal epithelium to the muscularis mucosae were examined. Cells that stained positive for gastrin G cells, somatostatin D cells, and chromogranin endocrine cells were counted in a minimum of three high power fields for each specimen, without reference to the clinical histories. Each cell was identified as a G, D, or endocrine cell type if a dark brown granular reaction was produced by the ABC method. The numbers of endocrine cells were evaluated by two pathologists (TK and YL). Ten well oriented vertical glands in each field were counted. The results were expressed as the total number of cells counted/10 adjacent glands. If the glandular structure was not well oriented, we counted two areas (the area with the most and the area with the least extensive 10 adjacent glands) and calculated the mean. The average number of positively counted cells for each 10

**Figure 1** Antral mucosa stained for gastrin positive G cells (original magnification, ×80).

**Figure 2** Antral mucosa stained for somatostatin positive D cells (original magnification, ×80).
vertical glands was compared between groups. Moreover, the distribution of the cells was also reported (even or uneven).

**Statistical analyses**

Data were analysed using the SPSS statistical package. The \( \chi^2 \) test was used to calculate the difference between G and D cells with respect to \( H. pylori \) status, the Mann-Whitney U test for analysing the difference in the grading of gastritis features, and the Spearman rank correlation test for analysing the correlation between different gastritis features and \( H. pylori \) status, and between G and D cells. A \( p \) value less than 0.05 was considered to be significant.

**RESULTS**

In total, 122 of the 194 patients who underwent endoscopy for dyspeptic complaints were used in our analyses. Table 1 shows the characteristics of the patients studied. The age and sex distribution did not differ significantly among the different groups.

**Helicobacter pylori status and histopathological changes**

\( H. pylori \) infection was found in 58 patients (58 of 122; 47.5%) with both procedures (CLO and Giemsa staining), with the remaining 64 individuals being \( H. pylori \) negative (64 of 122; 52.5%). Among the non-infected individuals, 47 had no histological changes, and 17 had features of chronic gastritis.

The histological scores for chronic inflammation, activity, atrophy, and intestinal metaplasia were higher in \( H. pylori \) positive than in \( H. pylori \) negative patients (\( p < 0.05 \)) and \( H. pylori \) infection was significantly associated with increased antral inflammation and activity (\( p < 0.01 \)). Mucosal atrophy was more prevalent in patients with \( H. pylori \) infection than those without. Antral atrophy was more pronounced than corpus atrophy (\( p < 0.01 \)).

**Expression of gastrin, somatostatin, and chromogranin**

There was no immunoreactivity when the primary antibodies were omitted from the staining procedure. The staining patterns for gastrin, somatostatin, and chromogranin were similar. Positive cells revealed cytoplasmic staining. Most of the positive cells were located in the middle third of the gastric glands, with few in the upper or deeper parts (figs 1, 2). However, in \( H. pylori \) positive patients, the distribution of chromogranin and gastrin positive cells moved slightly upwards to just beneath the foveolar gastric pit. G cells were only present in the antrum, whereas D cells and chromogranin positive cells were expressed both in the antrum and the corpus.

The \( H. pylori \) infected individuals had significantly higher numbers of immunoreactive G cells and lower numbers of immunoreactive D cells than those with non-infected gastritis and those with histological normal gastric mucosa. Significant differences existed between infected and non-infected individuals or normal groups both for immunoreactive G cells and D cells (table 2). A significant correlation was found between antrum immunoreactive G cells and D cells (correlation coefficient, 0.29) (\( p < 0.01 \)).

Figure 3 compares the density of immunoreactive G cells and D cells in each group. The number of immunoreactive G cells was highest among \( H. pylori \) infected patients and lowest among those with normal gastric mucosa. In contrast, the lowest score for immunoreactive D cells was seen in \( H. pylori \) infected patients. The mean density of immunoreactive G cells and immunoreactive D cells in patients with \( H. pylori \) negative chronic gastritis and with normal mucosa were not significantly different. Figure 4 summarises the density of immunoreactive G cells and D cells in relation to the density of \( H. pylori \). Although the number of immunoreactive G cells was higher and the number of D cells lower in those with \( H. pylori \) infection compared with the \( H. pylori \) negative group,
there was no evidence of a linear relation between \textit{H pylori} density and the density of either immunoreactive G or D cells. In contrast, the density of immunoreactive G and D cells was similar among those without inflammation and those with minimal inflammation (grade 1) (fig 5). Immunoreactive G cell density increased and D cell density decreased among those with moderate or severe inflammation (fig 5).

**Percentage of G and D cells in the stomach**

In addition to gastrin and somatostatin, chromogranin was used to identify all endocrine cells. The mean (SD) number of chromogranin positive cells was 49.1 (21) in \textit{H pylori} infected patients, 49.0 (19) in non-infected gastritis patients, and 50.5 (22) in those with normal mucosa (p > 0.05).

The percentage of G cells and D cells of all endocrine cells in the stomach was 52.0% and 17.5% in normal individuals, and 47.1% and 15% in the \textit{H pylori} negative group. However, in the \textit{H pylori} infected subjects, 70.1% of chromogranin positive cells were G cells and only 4.9% were D cells. The difference between \textit{H pylori} infected and non-infected or normal individuals was significant (p < 0.01; table 3).

**DISCUSSION**

Gastrin G and somatostatin D cells are the major endocrine cells in the stomach known to play an important role in acid secretion.\textsuperscript{10} Normally, about 50% of the endocrine cell population of the antrum is made up of G cells and 15% of D cells. In the corpus mucosa, enterochromaffin-like cells form a major proportion of the endocrine cells.\textsuperscript{11} However, no study has been carried out to define the exact percentages of these endocrine cells. In our study, approximately 52% of all the endocrine cells in the antrum were G cells and 17.5% were D cells. In the corpus, 8.3% of cells were D cells and no immunoreactive G cells were found. These results are comparable to other studies.\textsuperscript{12} We also confirmed that the percentages of G and D cells were altered in \textit{H pylori} infected gastric mucosa, with an increase in the proportion of G cells and a decrease in D cells.

Gastrin is released from G cells in the gastric antrum and acts via the circulation to stimulate acid secretion. Both \textit{H pylori} infection and acid secretion are related to the development of duodenal ulcers, prompting several investigators to examine the effect of \textit{H pylori} infection on the control of acid secretion. In 1989, Levi \textit{et al} reported that both basal and stimulated acid secretion plasma gastrin values were significantly higher in \textit{H pylori} positive patients than in \textit{H pylori} negative ones.\textsuperscript{13} These data were rapidly confirmed, and it was also shown that this increase was reversed after \textit{H pylori} eradication.\textsuperscript{14–17} Studies of antral biopsies from \textit{H pylori} infected individuals have shown that gastrin synthesis is increased.\textsuperscript{18}

“Overall, our data are consistent with the notion that the major defect leading to enhanced gastrin concentrations is related to disruption of the inhibitory effect of somatostatin on the G cell”\textsuperscript{19}

Normally, gastrin release is suppressed when the luminal antral pH falls below 3. In addition, there is an inhibitory control exerted on gastrin release by cholecystokinin. The inhibition of gastrin release exerted by both gastric acid and cholecystokinin is mediated mainly via the release of somatostatin by D cells within the antral mucosa. Several studies have now demonstrated lowered concentrations of somatostatin within the antral mucosa of subjects with \textit{H pylori} antral gastritis.\textsuperscript{10 12 13 15 16 27} In addition, somatostatin mRNA concentrations are lowered, indicating a reduced synthesis of this inhibitory hormone.\textsuperscript{11 13} These findings are consistent with our results that the density of D cells was significantly lower in \textit{H pylori} infected patients than in uninfected patients and normal individuals, whereas the density of G cells was significantly increased. The mechanism responsible for increased gastrin secretion and reduced somatostatin secretion remains unclear. Hypotheses have included a stimulatory effect of \textit{H pylori} urease on gastrin release, but this is unlikely because we were unable to show an association between \textit{H pylori} density and the density of immunoreactive G and D cells. The fact that there was an association with the severity of inflammation is more consistent with a role for cytokines released by inflammatory cells (for example, interleukin 1\beta, tumour necrosis factor \alpha, and interferon \gamma).\textsuperscript{26} The increase in inflammation associated with the presence of more virulent \textit{H pylori} types (such as those containing the Cag pathogenicity island) would also be expected to have a more profound effect on gastrin/ somatostatin homeostasis.

In some subjects, \textit{H pylori} infection results in antral predominant gastritis, with increased acid secretion and a propensity to duodenal ulcer disease; in others it results in body gastritis with low acid secretion and a predisposition to atrophic gastritis and gastric cancer, whereas in most subjects it results in mixed gastritis, with no overall change in acid secretion. The net effect on acid secretion presumably depends on which mechanism predominates. Because

*Significant difference (p<0.01).*
patients’ numbers in some subgroups were limited in our study, we could not analyse the group regarding the distribution as antral predominant gastritis, pangastritis, or corpus gastritis.

Overall, our data are consistent with the notion that the major defect leading to enhanced gastrin concentrations is related to disruption of the inhibitory effect of somatostatin on the G cell. It appears that H pylori antral gastritis increases gastrin by producing a deficiency of antral somatostatin and of the normal inhibitory influence of this hormone on gastrin release.

Our study showed that the total numbers of G cells were significantly higher in H pylori infection. However, others have suggested that the numbers are unchanged. The reasons for these differences are unclear. Possibilities include patient selection, as reflected in differences in the pattern and severity of gastritis among those examined. We found that the changes were more pronounced in those with the most severe inflammation. We speculate that the changes in cell numbers may in fact be a dynamic process. Initially, the density of G cells increases, but may later fall if antral atrophy occurs. Subsequent studies are needed to examine the pattern of D and G cells in a wider spectrum of H pylori infected gastric tissues, and to compare the possible role of different strains of H pylori.

ACKNOWLEDGEMENTS

We are grateful to Dr DY Graham for critical reading of the manuscript and his useful comments.
